# Bearing Capacity and Strengthening of a Multi-Storey Reinforced Concrete Hotel 

## ALEXANDROS BELIVANIS

Supervisor: Professor Vlassis Koumousis
A dissertation submitted in partial fulfilment of the requirements for the Degree of Master of Science in Analysis and Design of Earthquake Resistant Structures

Athens, July 2016

My originality declaration
"This dissertation entitled Bearing Capacity and Strengthening of a MultiStorey Reinforced Concrete Hotel for the fulfilment of the degree of M.Sc. in Analysis and Design of Earthquake Resistant Structures, has been made by myself based on references listed in appendices. All sources of information have been acknowledged by references including those from the internet."

## Acknowledgment

I would like to acknowledge my supervisor, Professor Vlassis Koumousis for his supervision during all the period I worked on this dissertation and because he gave me the opportunity to learn about this interesting subject.

#### Abstract

This project's aim is not only to study the bearing capacity of a multi-storey reinforced concrete hotel, but also to study its strengthening. The hotel constructed in 1967 in Greece in seismic zone 2 area ( $Z 2, a_{G R} / \mathrm{g}=0.24$ ) under the provision of the national codes of Members of Reinforced Concrete (1954) and of the Design Code for Earthquake Resistant structures (1959). It is a 5storey reinforced concrete building with underground floor, ground floor (two levels), mezzanine floor, approachable and non approachable roof. Its overall high is 27.53 m , including the non approachable roof, while the typical high of floors is 3.2 m . SAP2000 is used for the analyses of the building. Modal response spectrum analysis, nonlinear static (pushover) analyses and nonlinear dynamic time-history analyses are performed. Three pairs of acceleration time histories are used. They are the earthquakes events of Corinth (1981, magnitude: 6.6), Kalamata (1986, magnitude 6.2) and L'Aquila-Italy (2009 magnitude: 6.3). The acceleration time-histories are obtained by the PEER Ground Motion Data Base-Beta version. The acceleration time-histories are scaled. The assessment of the bearing capacity shows that the structure requires rehabilitation. The rehabilitation aim is to reach the life safety performance level. Nonlinear static (pushover) analyses and nonlinear dynamic time-history analyses are performed to the retrofitted structure, showing that the target-performance level is succeeded, when seismic action corresponding to seismic return period of 475 years, or the scaled L'Aquila, Corinth, Kalamata acceleration time-histories are imposed to the structure.

Table of Contents
CHAPTER 1 ..... 1
Introduction ..... 1
1.1 Motivation ..... 1
1.2 Research Objective ..... 1
1.3 Research Approach ..... 2
1.4 Report Outline. ..... 2
Chapter 2 .....  5
Assessment of the Bearing Capacity of Structures-Background Concepts ..... 5
2.1 Required Information for the Assessment of the Structure .....  5
2.1.1 General Information and History of the Building ..... 5
2.1.2 Required Input Data ..... 6
2.1.3 Materials ..... 6
2.1.4 Knowledge Level ..... 7
2.1.5 Confidence Factors ..... 7
2.2 Seismic Action for the Assessment of the Structure ..... 8
2.2.1 Seismic Action ..... 8
2.2.2 Combination of the Effects of the Components of the Seismic Action11
2.3 Methods of Analysis ..... 11
2.3.1 Modal Response Spectrum Analysis ..... 12
2.3.2 Nonlinear Static (Pushover) Analysis ..... 14
2.3.3 Nonlinear Time-History Dynamic Analysis ..... 17
2.4 Performance Based Design ..... 18
2.4.1 Rehabilitation Objectives ..... 20
2.4.2 Structural Performance Levels ..... 21
2.4.3 Capacity Curve ..... 22
2.4.4 Primary and Secondary Elements and Components ..... 22
2.4.5 Component Behaviour F- $\delta$ Curve ..... 23
2.4.6 Performance Levels of the Elements ..... 26
2.4.7 Performance Levels of the Structure ..... 29
2.4.8 Target Displacement Check ..... 30
2.4.9 Performance Point Estimation ..... 32
2.4.10 ATC-40 Methodology ..... 36
CHAPTER 3 ..... 45
Retrofit Strategies and Systems ..... 45
3.1 Introduction ..... 45
3.2 Technical Strategies ..... 46
3.2.1 Local Modification of Components ..... 47
3.2.2 Removal or Lessening of Existing Irregularities ..... 48
3.2.3 Global Structural Strengthening and Stiffening ..... 48
3.2.4 Reducing Earthquake Demands (mass reduction, seismic isolation, energy dissipation systems) ..... 49
3.3 Management Strategies ..... 50
3.4 Retrofit System Selection ..... 51
3.5 Traditional Methods for the Retrofitting of Buildings ..... 52
3.5.1 Addition of shear walls ..... 52
3.5.2 Addition of braces in Frames ..... 54
3.5.3 Extension of Existing Columns with additional Shear Walls ..... 54
3.5.4 Columns Retrofitting-The Application of Jackets to Columns ..... 55
CHAPTER 4 ..... 59
Modelling of the structure using SAP 2000 ..... 59
4.1 SAP2000 Overview ..... 59

## CHAPTER 1

## Introduction

### 1.1 Motivation

The majority of buildings constructed in Greece until the mid 80's are reinforced concrete buildings. A significant portion of those buildings have faced light or severe damages due to the earthquakes occurred during their lifetime (Spyrakos, 2004). The Design Code for Earthquake Resistant structures was introduced in Greece in 1959. However the buildings that were designed under its provisions, especially the multi-storey, do not have adequate resistance to earthquakes. Their members do not have adequate, ductility, most buildings do not have a lateral force resisting system in both directions and in many cases architectonic factors define the positions of the beams and columns, so the structural system do have many indirect supports (beam to beam) and do not have frames. Those structural systems may be adequate to transfer the vertical loads; however their resistance to seismic loads is inadequate. As a result, the buildings designed under the provision of the Design Code for Earthquake Resistant structures of 1959 or earlier, are extremely vulnerable to earthquakes and they may be dangerous for human or economic losses (Fardis et al. 2003).

Thus the study of the assessment of the bearing capacity of buildings and their strengthening is a very interesting subject and will be in high demand in the next few years in Greece.

### 1.2 Research Objective

The objective of this research is to study the methods of assessment of the bearing capacity of structures, the nonlinear static and the non linear dynamic analyses using performance based design. In addition its objective is to study the methods of seismic retrofitting and to apply the appropriate methods in order to rehabilitate the structure under examination.

### 1.3 Research Approach

In this paper the bearing capacity of a multi-storey reinforced concrete hotel is examined. Information about the assessment of the bearing capacity, the seismic actions, the methods of analyses, the performance based design and the retrofit strategies and systems is provided. After background information is given, the modelling of the structure in SAP2000 software is described and all the values that are used as inputs are set and explained. Furthermore, three types of analyses are performed. They are the modal response spectrum analyses, the nonlinear static (pushover) analysis and the non linear dynamic time-history analysis. The results of the analyses are discussed and the building is rehabilitated. The nonlinear static and the nonlinear dynamic analyses are performed for the retrofitted building.

### 1.4 Report Outline

The first chapter is an introduction to this study by explaining the motivation, the objectives and the research approach.

In the second chapter background information about the assessment of the bearing capacity of structures, the methods of analyses and the performance based design is provided.

In the third chapter information for the retrofit strategies and systems are included.

Chapter four consists of the modelling procedure in SAP2000. The history and description of the structure are explained and the material properties, the frame sections, the stiffness of the structure, the loads and the diaphragms are defined.

In the fifth chapter the modal response spectrum analysis is explained and its results are discussed.

In the sixth chapter the non linear static (pushover) analysis of the existing structure is explained and its results are provided and discussed.

Chapter seven consists of information about the non linear time-history analysis of the existing structure. In addition the acceleration time-histories are provided and the results are discussed.

In the chapter eight the interventions on the structure are explained.
In the ninth chapter the non linear static analysis of the retrofitted structure is explained and its results are discussed.

In the tenth chapter the non linear dynamic time-history analysis of the retrofitted structure is explained and its results are discussed.

Chapter eleven consists of the shear resistance checks.
In the chapter twelve the results of the analyses of the non retrofitted and retrofitted structure are compared and discussed.

In the chapter thirteen the summary and the concluding remarks are included.

## Chapter 2

## Assessment of the Bearing Capacity of Structures-Background Concepts

### 2.1 Required Information for the Assessment of the Structure

The assessment of existing structures follows the procedure:

- Collection of data and history of the structure
- Analyses
- Verification of limit states (KANEPE, 2013)

The goal of the assessment is to estimate the bearing capacity of the structure, and to testify whether the requirements provided by the standards are met (KANEPE, 2013).

A damaged structure should be assessed by a different procedure than nondamaged structures. The assessment of a non-damaged structure determines the rehabilitation need, in relation to the target performance. In case the structure is already damaged, the first step is the assessment of the structure at its current condition, which leads to the decision to repair it or not. The second step is the assessment of the repaired structure, which helps to decide whether the rehabilitation is necessary. (KANEPE, 2013)

### 2.1.1 General Information and History of the Building

In assessing the earthquake resistance of existing structures, the input data shall be collected from a variety of sources which include:

- Available documentation of the building
- Relevant generic data sources (e.g. contemporary codes and standards)
- Field investigations
- In-situ and/or laboratory measurements and tests (EN 1998-3, 2005).

### 2.1.2 Required Input Data

The required information is:

- The structural system and its compliance with the regularity criteria in EN 1998-1:2004, 4.2.3 should be identified. The information should be collected either from the original design drawings, or from on site investigation. Information on possible structural changes since construction should also be collected.
- The type of the building foundations should be identified.
- The ground condition as categorized in EN 1998-1:2004, 3.1 should be identified.
- Information about the mechanical properties and the condition of constituent materials, such as the overall dimensions and cross-sectional properties of the building elements should be collected.
- Information about identifiable material defects and inadequate detailing.
- Information on the seismic criteria used for the initial design. The value of the force reduction factor (q-factor) should also be known, if applicable.
- The present use of the building (with identification of its importance class, as described in EN 1998-1:2004, 4.2.5) should be described.
- Re-assessment of the imposed actions taking into account the use of the building.
- Information about any present or previous damage, if any, including earlier repair measures. (EN 1998-3, 2005)

### 2.1.3 Materials

Data for the current condition of the concrete and the reinforcement steel should be gathered. The necessary mechanical properties for the concrete are its compression strength (fc) and the modulus of elasticity (E), while for the reinforcement steel, they are the yield strength $f_{y}$, its tensile strength $\left(f_{t}\right)$ and its stain at maximum load $\left(\varepsilon_{u}\right)$ (KANEPE, 2013).

### 2.1.4 Knowledge Level

The engineer is able to decide the appropriate type of analysis and the appropriate confidence factor values, once the knowledge level is known.

KL1: Limited knowledge
KL2: Normal knowledge

## KL3: Full knowledge

The factors that determine the appropriate knowledge level are:

- Geometry: the geometry of the structural system, and of non- structural elements (e.g. masonry infill panels) that may affect the structural response.
- Details: the amount and detailing of the reinforcement in reinforced concrete and the connection of floor diaphragms to lateral resisting structure.
- Materials: the mechanical properties of the constituent materials.

### 2.1.5 Confidence Factors

The mean values of the material properties that are obtained from in-situ tests and from additional sources of information and are used in the calculation of the capacity, when capacity is to be compared with the demand for safety verification, shall be divided by the confidence factor, CF , for the appropriate knowledge level.

The mean values of the properties of the materials that are obtained from insitu tests and from additional sources of information shall be multiplied by the confidence factor, CF, for the appropriate knowledge level, when the determination of the properties to be used in the calculation of the force capacity (strength) of ductile components, delivering action effects to brittle components/ mechanisms, is requested (EN 1998-3, 2005).

The proposed values are: $\mathrm{CF}_{\mathrm{kL} 1}=1.35, \mathrm{CF}_{\mathrm{kL} 2}=1.20, \mathrm{CF}_{\mathrm{KL} 3}=1.00$

### 2.2 Seismic Action for the Assessment of the Structure

The aim of the assessment of the structure is to check whether an existing undamaged or damaged building satisfies the required limit state appropriate to the seismic action under consideration (EN 1998-3, 2005).

### 2.2.1 Seismic Action

The earthquake motion at a given point on the surface is represented by an elastic ground acceleration response spectrum, which is called an "elastic response spectrum".

Two orthogonal components which are assumed as being independent describe the horizontal seismic action. The two components are described by the same response spectrum (EN 1998-1, 2004).

In addition, time-history representation of the earthquake motion may be used (EN 1998-1, 2004).

Figure 2.1 Shape of the Elastic Response Spectrum (EN 1998-1:2004)

The values of periods $T_{B}, T_{C}, T_{D}$ and of the soil factor $S$, which describe the shape of the elastic response spectrum depend upon the ground type.

Table 2.1 Values of the Parameters describing the recommended Type 1 Elastic Response Spectra (EN 1998-1:2004, Greek National Annex)

| Ground Type | S | $T_{B}(\mathrm{~s})$ | $T_{C}(\mathrm{~s})$ | $T_{D}(\mathrm{~s})$ |
| :---: | :---: | :---: | :---: | :---: |
| A | 1 | 0.15 | 0.4 | 2.5 |
| B | 1.2 | 0.15 | 0.5 | 2.5 |
| C | 1.15 | 0.2 | 0.6 | 2.5 |
| D | 1.35 | 0.2 | 0.8 | 2.5 |
| E | 1.4 | 0.15 | 0.5 | 2.5 |

### 2.2.1.1 Design Spectrum for Elastic Analysis

The design of structures to resist seismic forces, lower than those that correspond to a linear elastic response is permitted, due to the capacity of structures to resist seismic actions in the non-linear range.

The reduction is achieved through the introduction of the behaviour factor q. As a result, explicit inelastic structural analysis in design is avoided. The ability of the structure to dissipate energy, though the ductile behaviour of its elements, and/or other mechanisms, is taken into account by performing an elastic analysis based on a reduced (by the behaviour factor q) response spectrum, with respect to the elastic one. Thus it is called a "design spectrum".

The design spectrum $\mathrm{S}_{\mathrm{d}}(\mathrm{T})$, for the horizontal components of the seismic actions, is defined as follows:

$$
\begin{align*}
& 0 \leq T \leq T_{B}: S_{d}(T)=a_{g} \cdot S \cdot\left[\frac{2}{3}+\frac{T}{T_{B}} \cdot\left(\frac{2,5}{q}-\frac{2}{3}\right)\right] \\
& T_{B} \leq T \leq T_{C}: S_{d}(T)=a_{g} \cdot S \cdot \frac{2,5}{q} \\
& T_{C} \leq T \leq T_{D}: S_{d}(T)\left\{\begin{array}{l}
=a_{g} \cdot S \cdot \frac{2,5}{q} \cdot\left[\frac{T_{C}}{T}\right] \\
\geq \beta \cdot a_{g}
\end{array}\right.  \tag{1-4}\\
& T_{D} \leq T: S_{d}(T)\left\{\begin{array}{l}
=a_{g} \cdot S \cdot \frac{2,5}{q} \cdot\left[\frac{T_{C} \cdot T_{D}}{T^{2}}\right] \\
\geq \beta \cdot a_{g}
\end{array}\right.
\end{align*}
$$

Where $S_{d}(T)$ is the design spectrum;
$T$ is the vibration period of a linear single-degree of freedom system;
$a_{g}$ is the design ground acceleration on type $\mathrm{A}\left(a_{g}=\gamma_{I} \cdot a_{g R}\right)$;
$T_{B}$ is the lower limit of the period of the constant spectral acceleration branch;
$T_{C}$ is the upper limit of the period of the constant spectral acceleration branch;
$T_{D}$ is the value defining the beginning of the constant displacement response range of the spectrum;
$S$ is the soil factor;
$\eta$ is the damping correction factor with a reference values of $\eta=1$ for $5 \%$ viscous damping; $\eta=\sqrt{10 /(5+\xi)} \geq 0,55$ where $\xi$ is the viscous damping ratio of the structure, expressed as a percentage. (EN 1998-1, 2004)
q is the behaviour factor;
$\beta$ is the lower bound factor for the horizontal design spectrum; $\beta=0.2$ (EN 19981:2004, Greek National Annex).

### 2.2.1.2 Time-History Representation

The motion due to an earthquake event can also be presented in terms of ground acceleration time-histories and related quantities (velocity and displacement) (CSi, 1995).

The samples should be carefully chosen to correspond to the seismogenetic features of the sources and the soil conditions of the site. The accelerograms may be recorded or generated through a physical simulation of source and travel path mechanisms. More information about the time-history analysis is given in section 2.3.3 (EN 1998-1, 2004).

### 2.2.2 Combination of the Effects of the Components of the Seismic Action

The horizontal components of the seismic action are taken as acting simultaneously. The square root of the sum of the squared values of the action effect due to each horizontal component can be used for the estimation of the maximum value of each action effect on the structure due to the two horizontal components of the seismic action.

Alternatively the effects of the horizontal components of the seismic action may be computed using the following combinations:

- $E_{E d x}{ }^{\prime}+{ }^{\prime} 0.30 E_{E d y}$
- $0.30 E_{E d x}{ }^{\prime}+{ }^{\prime} E_{E d y}$
(6) (EN 1998-1, 2004)
where ' + ' implies "to be combined with" and
$\mathrm{E}_{\mathrm{Edx}}$ are the action effects due to the application of the seismic action along the chosen horizontal axis of the structure.
$E_{\text {Edy }}$ are the action effects due to the application of the same seismic action along the orthogonal horizontal axis y of the structure (EN 1998-1, 2004).

### 2.3 Methods of Analysis

The effects of the seismic action, which are combined with the effects of the other permanent and variable loads in accordance with the seismic load combination, may be evaluated using one of the following methods:

- Lateral force analysis (linear)
- Modal response spectrum analysis (linear)
- Nonlinear static (pushover) analysis
- Nonlinear time-history dynamic analysis
- q-factor approach

Linear static procedure (lateral force analysis) is appropriate when higher modes effects are not significant, which is generally true for short, regular buildings.

Dynamic procedures are required for tall buildings, or buildings with torsional irregularities, or non-orthogonal systems. (FEMA 356, 2000)

The modal response spectrum analysis, the nonlinear static (pushover) analysis and the nonlinear time-history dynamic analysis are explained below.

### 2.3.1 Modal Response Spectrum Analysis

According to the modal response spectrum analysis the response of all modes of vibration which contribute significantly to the global response of the structure, should be taken into account. This claim is satisfied if either of the following can be demonstrated:

- the sum of the effective modal masses for the modes taken into account amounts at least $90 \%$ of the total mass of the structure;
- all modes with effective modal mass greater than $5 \%$ of the total mass are taken into account (EN 1998-1, 2004).

The above conditions should be met for each relevant direction, in case a spatial model is used (EN 1998-1, 2004). The sum of the effective modal masses (for all modes and a given direction) is equal to the mass of the structure ( CSi , 1995).

According to EN 1998-1, 2004 the response in two vibration modes i and j (including translational and torsional modes) may be taken as independent of each other, if the following criterion is met:
$T_{j} \leq 0.9 T_{i}$ where $T_{j}$ and $T_{i}$ are periods (with $T_{j} \leq T_{i}$ )
In case the above condition is met, so all relevant mode responses are considered independent of each other, the maximum value $\mathrm{E}_{\mathrm{e}}$ of a seismic action effect can be estimated by the use of the square root of the sum of the squares method (SRSS):

$$
E_{e}=\sqrt{\Sigma \mathrm{E}_{\mathrm{E} i}^{2}}
$$

(7) (EN 1998-1, 2004)
where:
$E_{E}$ is the seismic action effect under consideration (force, displacement, etc.);
$\mathrm{E}_{\mathrm{Ei}}$ is the value of the seismic action effect due to the vibration mode i .
In case the modal responses are not independent of each other, more accurate methods such as the "Complete Quadratic Combination" (CQC), should be used for the combination of the modal maxima (EN 1998-1, 2004).

Modal Analysis is used for the determination of the vibration modes of the structure. The modes are useful to understand the behaviour of the structure. In addition, they can be used as the basis for modal superposition in response spectrum analysis. The Eigenvector Analysis is the type of modal analysis that determines the undamped free-vibration mode shapes and frequencies of the structure. An excellent insight into the behaviour of the structure is provided by these natural modes (CSi, 1995).

Eigenvector analysis involves the solution of the generalized eigenvalue problem:
$\left[K-\Omega^{2} M\right] \Phi=0$
(8) (CSi, 1995)

Where $K$ is the stiffness matrix, $M$ is the diagonal mass matrix, $\Omega^{2}$ is the diagonal matrix of the eigenvalues and $\Phi$ is the matrix of the corresponding eigenvectors (mode shapes).

A natural vibration mode is determined by each eigenvalue-eigenvector pair. The eigenvalue is the square of the circular frequency $\omega$ for that mode.

A mass degree of freedom is any active degree of freedom that possesses translational mass or rotational mass moment of inertia (CSi, 1995).

The Response Spectrum Analysis is a statistical type of analysis. Its aim is to determine the likely response of the structure to seismic loading.

According to CSi (1995) the dynamic equilibrium equations that are associated with the response of the structure to ground motion are given by:
$K u(t)+C \dot{u}(t)+M \ddot{u}(t)=m_{x} \ddot{u}_{g x}(\mathrm{t})+m_{y} \ddot{u}_{g y}(\mathrm{t})+m_{z} \ddot{u}_{g z}(t)$
Where $K$ is the stiffness matrix, $C$ is the proportional damping matrix and $M$ is the diagonal mass matrix. $u, \dot{u}, \ddot{u}$ are the relative displacements, velocities and accelerations with respect to the ground respectively, $m_{x}, m_{y} m_{z}$ are the unit acceleration loads and $\ddot{u}_{g x}, \ddot{u}_{g y}, \ddot{u}_{g z}$ are the components of uniform ground acceleration.

Through the response spectrum analysis the likely maximum response to these equations is calculated. The information about the time that this extreme value occurs during the seismic loading is not available. To this it is necessary that the earthquake ground acceleration in each direction is given as a digitalized response-spectrum curve of pseudo-spectral acceleration response versus period of the structure.

The response quantities that are estimated include displacements, forces and stresses. A single, positive result is produced for each response quantity, even though accelerations may be specified in three directions. A statistical measure of the likely maximum magnitude for a specific response quantity is represented by each computed result. The actual response can be expected to vary within a range from this positive result to its negative (CSi, 1995).

Response spectrum analysis is performed using mode superposition method. A modal load case that computes the modes should be defined, and then that modal case should be referred in the definition of the response spectrum (Wilson and Button, (1982) cited in CSi (1995)).

### 2.3.2 Nonlinear Static (Pushover) Analysis

The main objective of the nonlinear static analysis is the estimation of inelastic deformation that is caused to the elements of the structure, under the imposed seismic action. A mathematical model of the structure, which incorporates the nonlinear load-deformation characteristics of its individual components and elements, should be subjected to monotonically increasing lateral loads, representing inertia forces in an earthquake, until a target displacement is
succeeded. The calculated displacements and internal forces should meet the acceptance criteria of the target performance level (FEMA 356, 2000).

The maximum displacement that is likely to be experienced during the design earthquake is represented by the target displacement. The calculated internal forces are reasonable approximations of the real ones expected during the design earthquake, due to the direct account for effects of material inelastic response by the mathematical model.

The node where the structure displacement is calculated, due to the imposed lateral loads, is called the "control node". It should be located at the centre of mass of the roof of the building. If a penthouse exists, the level of the control node should be at the level of the floor of the penthouse (FEMA 356, 2000).

The relation between the lateral displacement of the control node and the base shear force should be established for control node displacements ranging from zero to $150 \%$ of the target displacement, unless the building is earlier collapsed (KANEPE, 2013).

The gravity loads should be included in the mathematical model and combined with the lateral loads. The lateral loads should be imposed not only in positive, but also in negative direction. For the design, the maximum seismic effects shall be used.

The load-deformation response of each component along its length should be represented by a discretized analysis model, so as the identification of locations of inelastic actions is able.

All the lateral-force-resisting elements, either primary or secondary, should be included in the model.

It is important that the force-displacement behaviour of all components is included in the model, using full backbone curves that include strength degradation and residual strength, if any (FEMA 356, 2000).

Figure 2.2 Capacity Curves (ATC-40, 1996)

### 2.3.2.1 Limitations on Use of the Nonlinear Static Analysis

The non linear static analysis is permitted for structures that higher mode effects are not significant.

To determine if higher modes are significant, a modal response spectrum analysis shall be performed for the structure using sufficient modes to capture 90\% of the mass participation. In addition another response spectrum analysis should be performed, considering only the first mode participation. Higher mode effects shall be considered significant if the shear in any story resulting from the modal response spectrum analysis considering modes required to obtain $90 \%$ of mass participation exceeds $130 \%$ of the corresponding story shear considering only the first mode response.

If higher mode effects are significant, the non linear static procedure shall be permitted if a linear dynamic procedure (e.g. modal response spectrum analysis) is also performed to supplement the nonlinear static analysis (KANEPE, 2013).

### 2.3.2.2 Lateral Load Distribution

Lateral loads shall be applied in the plane of each floor diaphragm, in proportion to the distribution of inertia forces. The distribution of lateral inertia forces determines relative magnitudes of shears, moments, and deformations within the structure. During an earthquake, the distribution of these forces is going to
vary continuously, as portions of the structure yield and stiffness characteristics change. The distribution extremes depend on the intensity of the earthquake motion and the degree of the nonlinear response of the structure. Thus, using more than one lateral load pattern is recommended, in order to take into account the range of design actions that may occur during actual dynamic response (FEMA 356, 2000).

At least two vertical distributions of lateral load should be applied:

- A uniform distribution: The lateral loads at each level are proportional to the total mass of each level
- A modal pattern: The vertical distribution is proportional to the shape of fundamental mode in the direction under consideration (KANEPE, 2013).

Figure 2.3 Example of Lateral Loads Distribution (Psycharis, 2015)

### 2.3.3 Nonlinear Time-History Dynamic Analysis

Nonlinear time-history dynamic analysis may be used for the calculation of the response of the building in discrete time steps, using discretized recorded or synthetic time histories as base motion (FEMA 356, 2000).

The parameters of response should be calculated for each one time-history analysis performed. If three or more analyses are performed, the maximum
response of the parameter of interest should be used. If seven or more consistent pairs of horizontal time-histories are used, it is permitted to use the average of all responses of the parameter of interest (FEMA 356, 2000).

The nonlinear time-history analysis (dynamic) is similar to the nonlinear static analysis as it concerns the modelling approaches and the acceptance criteria. The main difference is that the design displacements are not established using a target displacement. Instead they are directly calculated through dynamic analysis using ground motion time histories (FEMA 356, 2000).

For the analysis of a spatial model, simultaneously imposed consistent pairs of earthquake ground motion records, along each of the horizontal axes of the building shall be permitted (FEMA 356, 2000).

Their values should be scaled to the value of $\mathrm{a}_{\mathrm{g}} . \mathrm{S}$ for the zone under consideration.

In addition, the accelerograms should comply with the following rules:

- At least 3 accelerograms should be used;
- The mean of the zero period spectral response acceleration values (calculated from the individual time histories) should not be smaller than the value of $\mathrm{a}_{\mathrm{g}} . \mathrm{S}$ for the site in question.
- In the range of periods between $0.2 T_{1}$ and $2 T_{1}$, where $T_{1}$ is the fundamental period of the structure in the direction where the accelerogram will be applied; no value of the mean 5\% damping elastic spectrum, calculated from all time histories, should be less than $90 \%$ of the corresponding value of the $5 \%$ damping elastic response spectrum (EN 1998-1, 2004).

### 2.4 Performance Based Design

The nonlinear static (pushover) analysis is focused on the generation of the capacity curve (or the pushover curve), which represents the lateral displacement as a function of the force applied to the structure. This process is
independent of the method used to calculate the demand and provides valuable insight for the engineer.

It can be combined with the "performance based design". Using the performance point or target displacement, the global response of the structure and the deformations of the individual components are compared to limits in light of the specific performance goal for the building (ATC-40, 1996).

Figure 2.4 Capacity Curve with Global Strength Degradation Modelled (ATC-40, 1996)

The "performance based design" is based on the definition of an acceptable level of damage (performance), considering the possibility to occur the "design earthquake". The method is focused on the real behaviour of the structure in relation with the level of the earthquake demand and the corresponding expected damage level. As a result, the optimum combination of safety and economy is ensured. In other words, a performance level describes a limiting damage condition which may be considered satisfactory for a given building and a given ground motion. (ATC-40, 1996)

On the one hand, the classic design methodology applied for the design of the modern earthquake resistant structures takes into account the behaviour of the structure before the yield point (elastic response) and does not take into
account the behaviour of the structure when it is damaged. The minimum safety level is achieved through the behaviour factor that is used. However in many cases this way of design may not guarantee the maximum safety level, especially for non regular buildings.

On the other hand, the performance based design is primarily applied for the bearing capacity assessment and the retrofitting of existing buildings. It is used by international codes such as the EN 1998-3, KANEPE, FEMA 356, ATC-40.

The behaviour of the structure from the appearance of the first damages to the collapse should be known. Thus the performance based design is applied in combination with non-linear analyses methods such as the non-linear static analysis (pushover), or the non-linear time history analysis (Psycharis, 2015).

### 2.4.1 Rehabilitation Objectives

A seismic rehabilitation objective shall be selected for the building, consisting of one or more rehabilitation goals. Each goal should consist of a Target Building Performance Level and an Earthquake Hazard Level (FEMA 356, 2000).

Prior to embarking on a rehabilitation program, an evaluation should be performed to determine whether the building in its existing condition, has the desired seismic performance capability (FEMA 356, 2000).

It is mentioned that the design of usual new buildings, according to the current codes corresponds to the B2 target of performance level (EAK 2000 cited in Psycharis (2015)).

Table 2.2 Rehabilitation Objectives (FEMA 356, 2000) (EN 1998-3, 2005)

|  |  |  | rformance Lev |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | Damage Limitation (DL) or Immediate Occupancy (IO) | $\begin{array}{ll} \hline \text { Life } & \text { Safety } \\ \text { (LS) } & \end{array}$ | Near Collapse (NC) or <br> Collapse <br> Prevention <br> (CP) |
|  | 20 \% (Mean Return Period 225 years) | A1 | B1 | G1 |
|  | 10\% (Mean <br> Return Period 475 years) | A2 | B2 | G2 |
|  | 2 \% (Mean Return Period 2475 years) | A3 | B3 | G3 |

### 2.4.2 Structural Performance Levels

## Limit State of Near Collapse (NC)

The structure is heavily damaged. Vertical elements are still capable to sustain vertical loads, however the residual lateral strength and stiffness is low. Most non-structural components have collapsed and large permanent drifts are present. It is likely that the structure will not survive another earthquake, even of moderate intensity (EN 1998-3, 2005). There is significant danger for people to be injured from broken elements inside or outside of the structure. Probably its repair is not feasible.

## Limit State of Significant Damage (SD) or Life Safety (LS)

The damages to the structure are significant. There is some residual lateral strength and stiffness, and vertical elements are capable of sustaining vertical loads. Non-structural components are damaged. Partitions and infills are not failed out of plane. Moderate permanent drifts are present. It is likely that the structure is uneconomic to be repaired and can sustain after-shocks of moderate intensity (EN 1998-3, 2005). Most of the damages can be repaired. Non-significant injuries may occur.

## Limit State of Damage Limitation (DL) or Immediate Occupancy (IO)

The building is lightly damaged. The structural elements do not face significant yielding and retain their strength and stiffness properties. Non-structural elements, such as infills and partitions, may show distributed cracking. However the damage is economically repaired. Permanent drifts are negligible and the structure does not need any repair measures (EN 1998-3, 2005).The building is functional during or immediately after the earthquake. There is no danger of injuries (Psycharis, 2015).

### 2.4.3 Capacity Curve

The relation between the base shear force and the displacement of the control node is called "capacity curve" (EN 1998-1, 2004).The limit states of the performance are defined on the capacity curve. The non-linear displacement of the centre of mass of the roof is calculated for several values and specific distribution of the lateral load (pushover analysis), considering the reduced stiffness of the elements that have exceeded their yield point (Psycharis, 2015).

### 2.4.4 Primary and Secondary Elements and Components

All the elements and components that affect the distribution of forces in a structure, or the lateral stiffness, shall be classified as primary or secondary, even if they are not part of the intended lateral-force resisting system (FEMA 356,2000 ).

## Primary elements and components

Primary elements and components are considered the ones that provide the capacity to the structure to resist collapse under seismic loading induced by ground motion in any direction (FEMA 356, 2000).

Nearly all the elements of a typical building, including many nonstructural components make a contribution to the building's overall stiffness, mass, and damping, and consequently to its response to earthquake ground motion. However not all of those elements are critical to the ability of the structure to resist collapse when subjected to strong ground shaking (FEMA 356, 2000).

## Secondary elements and components

The elements and components that do not contribute significantly in resisting earthquake effects because of low lateral stiffness, strength or deformation capacity are classified as secondary (FEMA 356, 2000).

For a given performance level, acceptance criteria for primary elements is typically more restrictive than those for secondary.

By the use of secondary elements classification, certain elements are allowed to experience greater damage and larger displacements than would otherwise be permitted for primary elements (FEMA 356, 2000).

### 2.4.5 Component Behaviour F- $\delta$ Curve

The inelastic behaviour of each element of the structure should be taken into account. On the $\mathrm{F}-\delta$ diagrams the limits of the performance levels are determined. The "F" may represent forces or moments while the " $\delta$ " may represent deformation, curvature or rotation. Flexural coexist with shear deformation at the reinforced concrete frames and the rotation of the edge sections are influenced by anchorage. Thus the best choice for F - $\delta$ is the bending moment M and the rotation angle $\theta$. $\theta$ is the rotation angle of the chord that connects the base and the top of a theoretical cantilever of length equal to shear length Lv. $\theta=\delta_{v} / L_{v}$ where $L_{v}=M / V(M=$ bending moment at the base,
$\mathrm{V}=$ shear force $), \delta_{\mathrm{v}}$ is the displacement at the top of the theoretical cantilever (Psycharis, 2015).

Figure 2.5 Definition of Rotation Angle $\boldsymbol{\theta}$ (Psycharis, 2015)

For deformation-controlled actions, a "backbone curve" should represent an upper bound to the forces and a drop in resistance when degradation becomes apparent in the cyclic data. The backbone curve is approximated by a multilinear "idealized" load deformation relation as shown in figure 2.6 (ATC-40, 1996).

Figure 2.6 Backbone Curve-Deformation Controlled Actions (Psycharis, 2015)

For force-controlled actions, the backbone curve represents a lower bound to the forces, followed by a drop in resistance to match cyclic data. Displacement ductility should not be shown in the "idealized" deformation relation, as shown in the figure 2.7 (ATC-40, 1996).

Figure 2.7 Backbone Curve-Force Controlled Actions (Psycharis, 2015)

Strengths and deformation capacities are defined for earthquake loadings that involve about three fully reserved cycles to the specified deformation level, in addition to similar cycles to lesser deformation levels (ATC-40, 1996).

The idealized " F - $\overline{\mathrm{\delta}}$ curve is generally taken into account as shown in the figure 2.8.

Figure 2.8 Idealized F- $\bar{\delta}$ curve of structural elements (Psycharis, 2015)
where:

## OA:

Linear response is considered between the points O (unloaded component) and an effective yield point $A$. The slope of the OA represents the elastic stiffness. It is mentioned that if the deformation is given as rotation angle, the value of $\delta_{y}$ $=\theta_{y}$ should be calculated taking into account the participation of shear deformation and the anchorage slip of bars as explained in EC8-3 and KANEPE.

## AB:

The $A B$ part represents the nonlinear response at reduced stiffness from $A$ to $B$. It is the plastic deformation of the component. At point B significant strength degradation begins and resistance to reserved cyclic lateral forces is no longer guaranteed beyond this deformation. The slope from A to B is typically small, representing phenomena such as stain hardening. However, the $A B$ is often considered totally horizontal, so the yield strength $F_{y}$ is equal to the ultimate strength $F_{u}$. The plastic deformation capacity is the ultimate minus the yield deformation: $\delta_{\mathrm{p}}=\delta_{\mathrm{u}}-\delta_{\mathrm{y}}$.

## CD:

The residual resistance of the component is represented by the CD part. Its estimation is difficult and it is usually assumed to be equal to $20 \%$ of the nominal strength. The purpose of this segment is to allow modelling of components that have lost most of their lateral force resistance, but they are still capable of sustaining gravity loads.

### 2.4.6 Performance Levels of the Elements

The limit states of the performance levels are defined on the capacity curve of each element according to the corresponding deformations $\delta_{d}$. For example, in the figure 2.8 the point E represents the performance level "life safety". The limit states of the performance levels are depended on the frame type (e.g. column, beam e.t.c). In addition the classification to deformation-controlled or
force-controlled and primary or secondary is taken into account (Psycharis, 2015).

For ductile components subject to deformation controlled actions, performance is measured by the relation of deformation demand to deformation capacity. For those components forces and stresses are of lesser importance (ATC-40, 1996).

For components subject to force-controlled actions, where brittle behaviour is expected, the main measure of performance is the force or stress level (ATC40, 1996).

According to EN 1998-3 (2005) the deformation capacity of beams, columns and walls are defined in terms of the chord rotation $\theta$. Thus the limit states of the performance levels of the elements are defined on the backbone curve of each element.

## Limit State of Near Collapse (NC)

The value of the chord rotation capacity (elastic plus inelastic part) at ultimate $\theta_{u}$ of concrete members under cyclic loading may be calculated from the following expression:

$$
\begin{equation*}
\theta_{u m}=\frac{1}{\gamma e l}\left(\theta_{y}+\left(\varphi_{u}-\varphi_{y}\right) L_{p l}\left(1-\frac{0.5 \cdot L_{p l}}{L_{v}}\right)\right) \tag{10}
\end{equation*}
$$

Where:

Өy is the chord rotation at yield.
$\Phi u$ is the ultimate curvature at the end section.

Фy is the yield curvature at the end section.
The value of the length $L_{p l}$ of the plastic hinge depends on how the enhancement of strength and deformation capacity of concrete due to the confinement is taken into account in the calculation of the ultimate curvature of the end section $\varphi_{u}$ (EN 1998-3, 2005).

## Limit State of Significant Damage (SD)

The chord rotation capacity corresponding to significant damage $\Theta_{\text {SD }}$ may be assumed to be $3 / 4$ of the ultimate chord rotation $\theta_{u}$ (EN 1998-3, 2005).

## Limit State of Damage Limitation (DL)

The capacity for this limit state used in the verifications is the yielding bending moment under the design value of the axial load.

In case the verification is carried out in terms of deformations the corresponding capacity is given by the chord rotation at yielding $Ө y$, evaluated as:

For beams and columns:

$$
\begin{equation*}
\theta_{y}=\varphi_{y} \cdot \frac{L v+a_{v} \cdot z}{3}+0.0013 \cdot\left(1+1.5 \frac{h}{L v}\right)+0.13 \cdot \varphi_{y} \frac{d_{b} \cdot f_{y}}{\sqrt{f_{c}}} \tag{11}
\end{equation*}
$$

And for walls of rectangular, T - barbelled section:

$$
\begin{equation*}
\theta_{y}=\varphi_{y} \cdot \frac{L_{v}+a_{v} \cdot z}{3}+0.002 \cdot\left(1-0.125 \cdot \frac{L_{v}}{h}\right)+0.13 \cdot \varphi_{y} \cdot \frac{d_{b} \cdot f_{y}}{\sqrt{f_{c}}} \tag{12}
\end{equation*}
$$

Where:
$\Phi_{y}$ is the yield curvature of the end section
$a_{\mathrm{v}} \mathrm{z}$ is the tension shift of the bending moment diagram with
z length of internal level arm, taken equal to d-d' in beams, columns or walls with barbelled or T-section, or to 0.8 h in walls with rectangular section, and
$a_{\mathrm{v}}=1$ if shear cracking is expected to precede flexural yielding at the end section (i.e. when the yield moment at the end section, $M_{y}$, exceeds the product of $L_{v}$ times the shear resistance of the member considered without shear reinforcement, $\mathrm{V}_{\mathrm{R}, \mathrm{C}}$, taken in accordance with EN 1992-1-1:2004, 6.2.2 (1)); otherwise, (i.e. if $M_{y}<L_{v} V_{R, C}$ ) $a_{v}=0$,
$f_{y}$ and $f_{c}$ are the steel yield stress and the concrete strength, respectively, both in MPa
d and $\mathrm{d}^{\prime}$ are the depths to the tension and compression reinforcement respectively, and
$d_{b l}$ is the (mean) diameter of the tension reinforcement.
The first term in above expressions, accounts for the flexural contribution. The second term represents the contribution of shear deformation and the third anchorage slip of bars. (EN 1998-3, 2005)

### 2.4.7 Performance Levels of the Structure

The procedure described above for each element, is followed by the determination of the limit states of the performance levels on the capacity curve of the structure. This step is not a clear procedure and requires engineering judgement. The reason is that a performance level for the whole structure is not always corresponding to the point that the first element of the structure reaches the corresponding performance level. A number of the structure elements may have reached a performance level, however the structure may still be below that level. Consequently, the engineer should assess the importance of damages of the elements to the structure behaviour. The classification of the elements into primary and secondary plays significant role. For example the limit states of the performance levels on the capacity curve, could be set for the first primary element that reaches each performance level (Psycharis, 2015).

Figure 2.9 Definition of the performance levels on the capacity curve of the structure (Psycharis, 2015)

### 2.4.8 Target Displacement Check

A displacement along the capacity curve that is consistent with the seismic demand should be calculated in order to determine compliance with a given performance level. The capacity spectrum method is suitable for this purpose. It is based on finding a point on the capacity spectrum, which also lies on the appropriate demand response spectrum, reduced for non linear effects. The condition, for which the seismic demand, imposed on the structure by the specified ground motion, is equal to the seismic capacity of the structure, is represented by the "performance point" (ATC-40, 1996).

The performance point may be estimated accurately by nonlinear time history analysis. However, specialized software is required, the analysis is time consuming and it is highly dependent on the time history used. Thus many nonlinear time-history analyses, using accelerograms of various characteristics are required in order to obtain reliable results.

In addition, methods such as the coefficient method or the nonlinear static (pushover) analysis may be used for the estimation of the target displacement. The nonlinear static analysis shall be applied in combination with other methods
such as the N2 method, the modal pushover, the adaptive pushover or the ATC40 , which is explained below.

Figure 2.10 Definition of the Target Displacement of the Equivalent Single-Degree of Freedom System (Psycharis, 2015)

Once the expected displacement of the structure (of the control node) is calculated, the relevant performance point is marked on the capacity curve, which is compared with the desirable performance level for the considered ground motion. Subsequently, it is checked if the target performance level is exceeded or not.

The same procedure shall be followed for each element, at its own "F- $\delta$ " curve. If the target performance level for some elements is exceeded, their rehabilitation is necessary and the whole procedure should be repeated.

As mentioned earlier, unless nonlinear dynamic time-history analysis is performed, the accuracy of the results obtained by alternative methods (the "static" methods) is not adequate. The reason is that they are based on the response of an equivalent single degree of freedom system and that the
estimation of the response at each floor level of the structure is based on a determined vertical distribution of lateral loads (Psycharis, 2015).

### 2.4.9 Performance Point Estimation

### 2.4.91 Equivalent single degree of freedom system

The equivalent single degree of freedom system is dependent on the distribution of the lateral loads, which are used for the generation of the capacity curve.

In general the following expression is used for the distribution of lateral loads:
$F i=V \cdot \frac{m_{i} \varphi_{i}}{\sum_{j} m_{j} \varphi_{j}}$
(13) (Psycharis, 2015)

Where: $V=\sum F_{i}$ is the base shear force.
This method is usually applied for planar motion of the structure to the seismic force direction, so the $\varphi_{i}$ factor represents the distribution of the displacements at the floor levels. Commonly, they are considered equal to the first mode value, however any other distribution, representative of the expected displacement of the structure, may be used. The values of the $\varphi_{\mathrm{i}}$ are normalized, so that the value at the top is equal to one: $\varphi_{\text {top }}=1$.

As long as the previous formula is used for the distribution of lateral loads and $\varphi_{\text {top }}=1$, the correspondence between the multi-degree and the single-degree of freedom systems (for forces, displacements, energy etc) is given by:
$Q=\Gamma \cdot Q^{*}$
(Psycharis, 2015)
where
$Q^{*}=$ the magnitude at the single degree of freedom system (e.g. force $\mathrm{F}^{*}$, displacement $\mathrm{d}^{*}$ )
$\mathrm{Q}=$ corresponding magnitude at the multi degree of freedom system (e.g. base shear force $V$, top displacement $\Delta$ )
$\Gamma=$ participation factor, which is given (for planar motion of the structure) by the expression:

$$
\Gamma=\frac{\sum m_{i} \varphi_{i}}{\sum m_{i} \varphi_{i}^{2}}
$$

(15) (Psycharis, 2015)

The numerator of the above expression is equal to the mass of the equivalent single-degree of system:

$$
\begin{equation*}
\mathrm{m}^{*}=\sum m_{i} \varphi_{i} \tag{16}
\end{equation*}
$$

Both the forces and the displacements are converted from a single-degree of freedom to a multi-degree of freedom system and vice versa, following the same rule, so the stiffness of the two systems is common. However the natural period of the equivalent single-degree of freedom system is not equal to the fundamental period of the multi-degree of freedom system (Psycharis, 2015).

### 2.4.9.2 Conversion of the capacity curve to the capacity spectrum

Prerequisite to use the capacity spectrum method is the conversion of the capacity curve, which is in terms of base shear force and roof displacement, to what is called a capacity spectrum, which is a representation of the capacity curve in Acceleration-Displacement Response Spectra (ADRS) format (i.e. $\mathrm{S}_{\mathrm{a}}$ versus $\mathrm{S}_{\mathrm{d}}$ ). The equations that are required for the transformation are (ATC-40, 1996):

$$
S_{a}=\frac{V}{a \cdot m_{t o t}}
$$

$(17,18)$ (Psycharis, 2015)

$$
S_{d}=\frac{\Delta}{\Gamma} \quad \text { or } \quad S_{d}=\frac{\Delta}{\Gamma \cdot \varphi_{\text {top }}} \text { if } \varphi_{\text {top }} \neq 1
$$

Where:

V is the base shear force of the multi-degree of freedom system
$m_{\text {tot }}=$ total mass of the multi-degree of freedom system
$a=$ modal mass coefficient for the first natural mode (ATC-40, 1996)
$\Delta=$ displacement of the top
$a=\frac{\left[\sum m_{i} \varphi_{i}\right]^{2}}{m_{\text {tot }} \sum \sum m_{i} \varphi_{i}^{2}}=\frac{\Gamma \cdot \sum m_{i} \varphi_{i}}{m_{\text {tot }}}=\Gamma \cdot \frac{m^{*}}{m_{\text {tot }}}$
(19) (Psycharis, 2015)

Figure 2.11 Example Modal Participation Factors and Modal Mass Coefficients (ATC40, 1996)

As shown in the figure 2.11, the modal mass coefficient and the participation factor, vary according to the relative inter-story displacement over the building height (ATC-40, 1996).

The general process for converting the capacity curve to the capacity spectrum, that is, converting the capacity curve into the ADRS format, is to first calculate the modal participation factor $\Gamma$ and the modal mass coefficient a using the equations above. Then for each point on the capacity curve, V , $\delta$ top, the associated point $S_{a}, S_{d}$ on the capacity spectrum is calculated using the equations $(17,18)$ (ATC-40, 1996).

The traditional $S_{a}$ versus $T$ representation of response spectra is familiar to the majority of engineers. However the $S_{a}$ versus $S_{d}$ (ADRS) representation is less familiar to them. Lines radiating from the origin have constant period in the

ADRS format. The period T , for any point of the ADRS spectrum, can be calculated by the relationship:

$$
\begin{equation*}
T=2 \pi \cdot \sqrt{\frac{S_{d}}{S_{a}}} \tag{20}
\end{equation*}
$$

Similarly, for any point on the traditional spectrum, the spectral displacement $\mathrm{S}_{\mathrm{d}}$ can be computed using the formula:

$$
\begin{equation*}
S_{d}=\frac{S_{a} \cdot T^{2}}{4 \pi^{2}} . \tag{21}
\end{equation*}
$$

These two relationships are the same formula arranged in different ways.

Figure 2.13 shows the same capacity spectrum superimposed on each of the response spectra plots shown in figure 2.12. Following along the capacity spectrum, the period is constant at $T 1$, up until point $A$. When point $B$ is reached, the period is T2. This is important since it indicates that as the structure undergoes inelastic displacement, the period lengthens. The lengthening period is clear on the ADRS plot (remembering that lines of constant period radiate from origin), even if it is more apparent on the traditional spectrum plot (ATC-40, 1996).

Figure 2.12 Response Spectra in Traditional and ADRS formats (ATC-40, 1996)

Figure 2.13 Capacity Spectrum superimposed over Response Spectra in Traditional and ADRS formats (ATC-40, 1996)

### 2.4.10 ATC-40 Methodology

Three procedures of the methodology are proposed, which results are similar. (Psycharis, 2015). In the following the procedure $A$ is described, which is the most direct application of the concepts and relationships mentioned above. This procedure is iterative. It is more an analytical method than a graphical method (ATC-40, 1996). Its steps are:

## 1) Elastic Response Spectrum Conversion

The 5\% damped (elastic) response spectrum, appropriate for the site, should be developed and transformed into Acceleration Displacement Response Spectra (ADRS) (Psycharis, 2015) using the following equations:

$$
\begin{equation*}
S_{a}=\frac{4 \cdot \pi^{2}}{T^{2}} \cdot S_{d} \tag{22}
\end{equation*}
$$

$$
\begin{equation*}
S_{d}=\frac{T^{2}}{4 \cdot \pi^{2}} \cdot S_{a} \tag{23}
\end{equation*}
$$

$T=2 \pi \sqrt{\frac{S_{d}}{S_{a}}}$
(24) (Psycharis, 2015)
2) Generation of the capacity curve of the structure and conversion to capacity spectrum

The capacity curve of the structure should be found and transformed into a capacity spectrum (ADRS format) of the equivalent single-degree of freedom system as mentioned above. The capacity spectrum and the 5\% damped response spectrum should be plotted on the same chart.

## 3) Selection of a trial performance point

The trial performance point is estimated by the engineer to develop a reduced demand response spectrum. A line is drawn up from the origin, at the stiffness that corresponds to cracked sections (effective stiffness). The intersection of the line and the elastic spectrum ( $5 \%$ damped) determines the displacement $d_{1}$ of the equivalent single-degree of freedom system. For displacement $d_{1}$ is estimated the trial performance point on the capacity spectrum as shown in the figure, and the corresponding acceleration $\mathrm{a}_{1}$ (Psycharis, 2015).

Figure 2.14 Calculation of the first trial performance point (Psycharis, 2015)

## 4) Construction of Bilinear Representation of Capacity Spectrum

The definition of the first performance point is followed by a bilinear representation of the capacity spectrum. It is necessary in order to estimate the effective damping and appropriate reduction of the spectral demand. If the capacity spectrum is found to intersect the reduced response spectrum at the estimated point, then this is the performance point (ATC-40, 1996).

To construct the bilinear representation, a line back from the trial performance point should be drawn. The slope of the line should be such, that when it intersects the first line, drawn up before from the origin at the stiffness that corresponds to cracked sections, the area designated $\mathrm{A}_{1}$ in the figure should be approximately equal to the area designated $\mathrm{A}_{2}$. The intent of setting the areas $A_{1}$ and $A_{2}$ equals is to have equal area under the capacity spectrum and its bilinear representation, that is, to have equal energy associated with each curve (ATC-40, 1996). The intersection of the first and second line determines the yield point, according to the bilinear curve, and its coordinates on the plot are the yield displacement $\delta_{y}$ and the yield acceleration $a_{y}$ (Psycharis, 2015).

Figure 2.15 Construction of Bilinear Representation of Capacity Spectrum (Psycharis, 2015)

## 5) Estimation of effective damping and reduction of 5\% damped response spectrum

The damping occurring when a structure is driven into the inelastic range by an earthquake ground motion is a combination of viscous damping (that is inherent in the structure) and the hysteretic damping (ATC-40, 1996).

$$
\begin{equation*}
\zeta_{e f f}=\zeta_{e l}+\zeta_{\text {hyst }} \tag{25}
\end{equation*}
$$

Where
$\zeta_{e l}=$ viscous damping inherent in the structure (5\% for reinforced concrete structures)
$\zeta_{\text {hyst }}=$ hysteretic damping due to inelastic behaviour of the structure (Psycharis, 2015)

Hysteretic damping is related to the area inside the loops formed when the earthquake force (base shear) is plotted against the structure displacement (ATC-40, 1996).

Figure 2.16 Calculation of hysteretic damping according to Chopra cited in Psycharis (2015)

The hysteretic damping can be calculated as (Chopra 1995):
$\zeta_{\text {hyst }}=\frac{1}{4 \pi} \cdot \frac{E_{D}}{E_{S 0}} \Rightarrow \zeta_{\text {hyst }}=\frac{0.637 \cdot\left(a_{y} \cdot \delta_{u}-\delta_{y} \cdot a_{u}\right)}{a_{u} \cdot \delta_{u}}$
(26) (Psycharis, 2015)
where
$E_{D}=$ energy dissipated by damping
$\mathrm{E}_{\mathrm{s} 0}=$ maximum strain energy
As shown in the figure $2.16, E_{D}$ is the area enclosed by a single hysteresis loop. In other words it is the energy dissipated by the structure in a single cycle motion.
$\mathrm{E}_{s 0}$ is the area of the hatched triangle. It is the maximum strain energy associated to that cycle of motion (ATC-40, 1996).

The hysteretic damping can be used to estimate the effective damping of the structure.

The idealized hysteresis loop shown in the figure overestimates the effective damping, unless the building is ductile (concrete buildings are not typically ductile structures), subjected to ground shaking of short duration (not enough cycles to degrade elements significantly) and with effective damping less than $30 \%$. The overestimation of realistic levels of dumping occurs because the actual hysteresis loops are imperfect. They are reduced in area, or pinched.

Thus, according to ATC-40 a damping modification factor, $k$, is used. It is a measure of how well is the actual building hysteresis represented by the idealized hysteresis loop shown in the figure, either initially, or after degradation.

The structural behaviour of the building determines the к-factor. However the structural behaviour of the building is dependent on the duration of the ground shaking and on the quality of the seismic resisting system. Values for the кfactor and the types of structural behaviour are given in the tables.

Finally the effective damping is:

$$
\begin{equation*}
\zeta_{e f f}(\%)=5+\frac{63.7 \cdot \kappa \cdot\left(a_{y} \cdot \delta_{1}-\delta_{y} \cdot a_{1}\right)}{a_{1} \cdot \delta_{1}} \tag{27}
\end{equation*}
$$

The effective damping can be used for the calculation of the spectral reduction factors, which are used for the decrease of the elastic ( $5 \%$ damped) response spectrum to a reduced response spectrum with damping greater than $5 \%$ of critical damping (ATC-40, 1996).

The equations of the reduction factors are given by:

$$
\begin{aligned}
& S R_{A}=\frac{1}{B_{S}}=\frac{3.21-0.68 \cdot \ln \zeta_{\text {eff }}}{2.12} \geq S R_{A \cdot \min } \\
& S R_{V}=\frac{1}{B_{L}}=\frac{2.31-0.41 \cdot \ln \zeta_{\text {eff }}}{1.65} \geq S R_{V \cdot \min }
\end{aligned}
$$

$(28,29)$ (Psycharis, 2015)
Table 2.3 Minimum values of reduction factors (Psycharis, 2015)

| Structural <br> Type | Behaviour | $\mathrm{SR}_{\text {A.min }}$ |
| :--- | :--- | :--- |
| $\mathrm{SR}_{\text {L.min }}$ |  |  |
| A | 0.33 | 0.50 |
| B | 0.44 | 0.56 |
| C | 0.56 | 0.67 |

Then the reduced demand spectrum is produced, by multiplication of the reduction factors with the elastic spectrum (5\% damping). The $\mathrm{SR}_{\mathrm{A}}$ and $\mathrm{SR}_{\mathrm{L}}$ are multiplied with the parts that correspond to the constant acceleration and velocity, respectively.

The intersection point between the reduced response spectrum for $\zeta=\zeta_{\text {eff }}$ and the capacity spectrum is the new trial performance point. The projection of this point to the axes $S_{a}$ and $S_{d}$, defines the new acceleration $a_{2}$ and the new displacement $\delta_{2}$, respectively (Psycharis, 2015).

Figure 2.17 Construction of elastic response spectrum for $\zeta=\zeta_{\text {eff }}$ and calculation of new performance point

## 6) Intersection of Capacity Spectrum and Demand Spectrum

It is an iterative procedure. Adequate tolerance must be succeeded. If the demand spectrum intersects the capacity spectrum within acceptable tolerance, then the trial performance point is the performance point and its displacement represents the maximum structural displacement of the equivalent single-degree of freedom system, expected for the demand earthquake (ATC-40, 1996).

The acceptable tolerance criterion is:
$0.95 \cdot \delta_{1}<\delta_{2}<1.05 \cdot \delta_{1}$

If the acceptable tolerance is not succeeded, then a new $a_{i}, \delta_{i}$ point is selected and the process is repeated from the step 4.

## 7) Target displacement of the structure

The displacement of the top of the structure, which corresponds to the displacement $\delta$ of the equivalent single degree of freedom system, is calculated by the equation:

$$
S_{d}=\frac{\Delta}{\Gamma} \quad \text { or } \quad S_{d}=\frac{\Delta}{\Gamma \cdot \varphi_{\text {top }}} \quad \text { if } \quad \varphi_{\text {top }} \neq 1
$$

(30) (Psycharis, 2015)

Solving for $\Delta$ and taking into account that $\mathrm{S}_{\mathrm{d}}=\delta=$ the target displacement

## CHAPTER 3

## Retrofit Strategies and Systems

### 3.1 Introduction

Once the seismic evaluation of the structure has been conducted and the presence of unacceptable seismic deficiencies has been detected, the retrofit strategy should be decided. For most buildings, acceptable design solutions may result by a number of alternative strategies and systems. The most favourable solutions among a number of feasible and applicable alternatives should be decided by the engineer together with the owner (ATC-40, 1996).
"A retrofit strategy is a basic approach adopted to improve the probable seismic performance of the building or otherwise reduce the existing risk to an acceptable level" (ATC-40, 1996).To obtain seismic risk reduction, both technical and management strategies may be employed. Approaches such as increasing building strength, correcting critical deficiencies, altering stiffness and reducing demand, are included in technical strategies. Approaches such as the change of occupancy, incremental improving and phased construction are included in the management strategies (ATC-40, 1996).
"A Retrofit system is the specific method used to achieve the selected strategy" (ATC-40, 1996). If the basic strategy, for example, is to increase building strength, the addition of new shear walls, thickening of existing shear walls, or addition of braced frames, may be used to accomplish this strategy. The selection of a specific system in order to evaluate the applicability of a given strategy is not necessary. However it is necessary to select a specific system in order to complete a design (ATC-40, 1996).

Systems and strategies are sometimes being confused by the engineers. Strategies are related to the modification or control of the basic parameters that affect the earthquake performance of a building. The building stiffness, strength, deformation capacity, ability to dissipate energy, the strength of
ground motion, the occupancy and the contents exposure within the building are included. Strategies can also include combinations of those approaches. Retrofit systems are the specific methods, used to implement the strategies. For example the addition of shear walls or braced frames to increase stiffness and strength, or the use of confinement jackets to enhance deformability (ATC-40, 1996).

### 3.2 Technical Strategies

The basic demand and response parameters of the building for the design earthquake are modified by technical strategies (ATC-40, 1996).

Lateral displacements experienced by the building as it responds to earthquake ground motion, lead to deformations of each individual element. The element deformations remain elastic, at low levels of response, and no damage is occurring. However, at higher levels of response, elements deformations exceed their linear elastic capacities and the building experience damages. A building must have a complete lateral force resisting system, capable of limiting earthquake-induced lateral displacements to levels that the damage sustained by the elements of the building will be within acceptable levels for the indented performance objective, in order to provide reliable seismic performance. The mass, stiffness, damping, the deformation capacity of the elements, the strength and character of the ground motion, are the basic factors that affect the lateral force resisting system of the building.

The technical strategies provide for improved seismic performance by directly operating on these basic response factors, either individually or in concert. The traditional approaches to seismic retrofitting-the addition of braced frames and shear walls-operate in building stiffness and strength. Energy dissipation systems operate on the structure damping capability. Base isolation operates on the character and strength of ground motion transmitted to the structure (ATC40, 1996).

Furthermore, although not specifically required by any of the strategies, it is extremely beneficial for the retrofitted lateral-force resisting system to have an
appropriate level of redundancy. As a result, any localized failure of a few elements of the system will not lead to local collapse or instability. The redundancy should be considered when developing retrofitting designs. (FEMA $356,2000)$

### 3.2.1 Local Modification of Components

Some elements may not have adequate strength, toughness or deformation capacity to satisfy the retrofit objective, although the building may have substantial strength and stiffness. In such a case, local modification of the elements that are inadequate shall be performed. The basic configuration of the lateral-force resisting system should be retained. Local modifications could be the improvement of component connectivity, deformation capacity and component strength (FEMA 356, 2000).

In addition, local strengthening may be applied to the under-strength elements or connections, without affecting the overall structure. Measures such as cover plating steel beams or columns, plywood sheathing to an existing timber diagram could be included. Such measures increase the strength of the element or component and allow it to resist more earthquake-induced force before the onset of damage.

Local measures that intend to improve the deformation capacity or ductility of the element make it able to resist large deformation levels. For example, the placement of a confinement jacket around a reinforced concrete column for the improvement of its ability to deform without spalling or degrading reinforcement slices could be used. In addition the reduction of the cross section to increase the flexibility and response displacement capacity could be used (FEMA 356, 2000). The increase of deformation capacity is more efficient when the number of elements that require modification is low. Otherwise, it may be extremely costly and cause significant problems to the occupants of the building, during the construction period (Spyrakos, 2004).

### 3.2.2 Removal or Lessening of Existing Irregularities

It can be detected by reviewing the results of the nonlinear analysis, by examining the distribution of structural displacements and inelastic deformation demands. If they are non uniform with disproportionally high values within one storey relative to the adjacent story, or at one side of the building relative to the other, then an irregularity exists.

Irregularities are common. However they are not always caused by the presence of a discontinuity in the structure, as for example the termination of a perimeter shear wall above the first story. Often, the demands predicted by the analysis may be reduced to acceptable levels by simple removal of the irregularity.

The addition of braced frames, or shear walls are effective corrective measures for removal or reduction of irregularities, such as soft or weak storeys. Moment frames, braced frames, or shear walls could be used to balance the distribution of mass and stiffness within a storey if torsional irregularities exist. Another corrective measure against irregularities may be the partial demolition. Portions of the structure, such as setback towers, or side wings, that may create the irregularity, could be removed. However the last measure has significant impact on the appearance of the structure (FEMA 356, 2000).

### 3.2.3 Global Structural Strengthening and Stiffening

It can be a great retrofitting strategy, if the deficiencies shown by the analysis are related to excessive lateral deflection of the building, and critical primary elements have inadequate ductility to resist the resulting deformations. By structural stiffening, the deformation demand is reduced (Spyrakos, 2004).

Effective measures for adding stiffness are the construction of new braced frames or shear walls within an existing structure (FEMA 356, 2000).

If there is an unacceptable performance deficiency in structural strength, global strengthening can be an effective rehabilitation strategy. This can be identified when the onset of global inelastic behaviour occurs at levels of ground shaking
that are substantially less than the selected level of ground shaking, or inelastic deformation demands are present throughout the structure. The threshold of ground motion at which the onset of damage occurs is possible to be raised by providing supplemental strength to such a lateral-force resisting system. Effective elements for this purpose are the shear walls and the braced frames. However they may be significantly stiffer than the structure to which they are added, which requires their design to provide nearly all of the structure's lateral resistance. On the other hand, moment-resisting frames are more flexible, consequently they may be more compatible with existing elements in some structures. However, such flexible elements may not become effective in the building response until existing brittle elements have already been damaged (FEMA 356, 2000).

If the strength increase is succeed without the increase of stiffness, for example by the use of FRP, then the retrofitted structure can sustain higher seismic actions, before damaging.

The global structural stiffening and strengthening are strategies usually applied simultaneously, since the majority of systems which increase the strength of the structure, such as the addition of shear walls, increase its stiffness, as well (Spyrakos, 2004).

### 3.2.4 Reducing Earthquake Demands (mass reduction, seismic isolation, energy dissipation systems)

### 3.2.4.1 Mass Reduction

The amount of force and deformation induced in a structure by ground motion is controlled by mass and stiffness. The reduction of mass may be an effective strategy of retrofitting, if deficiencies attributable to excessive building mass, global structural flexibility or global structural weakness are shown by the results of a seismic evaluation. The force and deformation demand produced by earthquakes can be reduced by mass reduction, so it can be used instead of structural strengthening and stiffening. Mass can be reduced in many ways, such as the demolition of upper stories, replacement of heavy cladding and
interior partitions, or removal of heavy storage and equipment loads (FEMA 356, 2000).

### 3.2.4.2 Seismic isolation

According to the seismic isolation strategy, compliance bearings are inserted between the superstructure and its foundations. In this way the structure above the bearings is translated nearly as a rigid body, since most of the deformation induced in the isolated system by the ground motion occurs within the compliant bearings, which are especially designed to resist these concentrated displacements. Moreover, most bearings have excellent energy dissipation characteristics (damping). The result is that the demand on the existing elements of the structure is greatly reduced. Thus seismic isolation is an appropriate strategy to achieve enhanced retrofitting objectives, like the protection of historic fabric, valuable contents, and equipment, or for buildings that contain important operations and functions. This strategy is more effective for relatively stiff buildings with low profiles and larger mass. It is less effective for light flexible structures (FEMA 356, 2000).

### 3.2.4.3 Supplemental Energy Dissipation

It is effective when excessive deformations due to global structural flexibility are occurred in a building. Technologies such as fluid viscous dampers (hydraulic cylinders), yielding plates, or friction pads allow the energy imparted to the structure by the ground motion to be dissipated in a controlled manner. The energy is dissipated by those devices, when they undergo significant deformation (or stroke), which requires that the structure experience substantial lateral displacements. Thus, those systems are most effective in structures that are relatively flexible and have some inelastic deformation capacity. They are most commonly installed in structures as components of braced frames (FEMA $356,2000)$.

### 3.3 Management Strategies

Management strategies are mainly controlled by the owner of the building, rather than the engineer. They are categorized in those strategies that affect
the acceptability of the probable performance of the building, and in those that regulate the way in which a technical strategy is implemented. The occupancy change, the demolition, the temporary retrofit, the phased retrofit, the retrofit while occupied, the retrofit while vacant, the exterior retrofit and the interior retrofit are included.

The management strategies are very important and affect the way a seismic risk reduction project is executed. They should be considered by the engineer in collaboration with the owner, since the last one probably do not have the relevant knowledge and may be unaware of the available alternative strategies (ATC-40, 1996).

### 3.4 Retrofit System Selection

The selection of the optimum retrofit system should be based on the established performance objectives which are desired for the building, and the existing deficiencies relative to those performance objectives. Once those have been determined, the evaluation of each of the strategy is necessary, to determine whether they are technically and practically capable of mitigating the deficiencies (ATC-40, 1996).

Summarizing the information provided above, the retrofit system selection is dependent on the desired performance objective, as follows:

Once the objective is the increase of stiffness and strength of the structure, the most effective method of retrofitting is the addition of shear walls. It is followed by the addition of braced frames, the extension of the existing columns with additional shear walls and the use of FRPs.

Once the objective is the improvement of the ductility, then the proposed method is the addition of confinement jackets to the columns that are inadequate, or the use of FRP's.

Once the objective is the improvement of the strength, stiffness and ductility of the structure simultaneously, then all of the methods of seismic retrofit can be
used, taking into account the desired level of improvement for each of the above (Spyrakos, 2004).

Usually the optimum solution, technically and in terms of cost, is a combination of the proposed retrofit systems (Spyrakos, 2004).

### 3.5 Traditional Methods for the Retrofitting of Buildings

As mentioned above, the basic approaches for seismic retrofitting of buildings are either the intervention to the structure as a whole, so as the stress at its weak elements will be reduced, or the retrofit of the weak elements of the structure. Usually the first is selected when the elements that are not adequate are too many (Fardis et al. 2003).

The most common methods of global retrofitting of a structure, which are explained in the following, are:

- The addition of shear walls
- The addition of braces in frames
- Extension of existing columns with additional shear walls

While the most common method of local retrofitting is:

- The application of jackets to columns

No matter which one of the above methods is selected, the new components must be connected to the existing structure. Thus special checks are necessary, to guarantee that the connection between the existing and the new materials can transfer the forces adequately (Fardis et al.2003).

### 3.5.1 Addition of shear walls

It is considered the most efficient method of increasing strength and stiffness of the structure. The number of additional shear walls and their position in the structure are the most crucial factors.

The techniques used for the addition of shear walls are:

- In-situ constructed shear walls
- Pre-cast walls (panels)
- Masonry of solid clay bricks or concrete masonry units
- Reinforcement anchored to the beams

Figure 3.1 Addition of Shear Wall (KANEPE, 2013)

Figure 3.2 Effectiveness of Structural Walls and Bracings (Sugano (1989) cited in Fardis et al (2003))

### 3.5.2 Addition of Braces in Frames

This method can make a significant contribution not only to the increase of the strength and stiffness of the existing structure, but also to its ductility. Usually these systems are made of steel (Fardis et al.2003). The diagonals work in axial stress and therefore call for minimum member sizes in providing stiffness and strength against horizontal shear (Viswanath et al.2010).

It is used in a similar way as in steel structures. Its application to industrial buildings or in soft-storeys in the ground floor of buildings is easy. Its self-weigh is low and it can be constructed quickly (Fardis et al.2003).

In addition, this system offers the ability to accommodate openings. If it is realized with external steel systems (external bracing), the minimum disruption of the full operationality of the building is obtained. There are two types of bracing systems, concentric bracing system and eccentric bracing system.

Figure 3.3 Steel Bracings in Frames (Fardis et al.2003)

### 3.5.3 Extension of Existing Columns with additional Shear Walls

It is an efficient way to increase the ductility of the structure. Furthermore it offers moderate increase of strength and stiffness. It is applied to carefully selected locations of the structure, usually combined with retrofitting of those columns which have inadequate strength and/or ductility.

The shear wall is added towards the direction that the resistance of the structure is inadequate. The addition of shear walls in two directions is common in corner columns.

The shear walls are usually constructed by cast-concrete or they are pre-cast. Unloading of the structure before their construction is recommended, so the shear walls would be able to take part of the vertical loading.

This method is widely applied in Greece, because no specialized personnel are required. Moreover, the uncertainties as it concerns the analysis are much lesser that those of the other methods described above (Fardis et al.2003).

Figure 3.4 Addition of shear walls in the sides of existing columns (Fardis et al.2003)

### 3.5.4 Columns Retrofitting-The Application of Jackets to Columns

It is the most common method of local retrofitting. The column retrofit is required when the elements have to take loads that exceed their strength. There are two main categories of methods for column retrofitting. The first is the retrofit of columns by increase of their sections and is applied by the application of jackets to the columns. The second one is the retrofit by providing confinement (Spyrakos, 2004).

### 3.5.4.1 Concrete Jacketing

Concrete jacketing technique is applied by the enlargement of the section of the existing concrete, by adding new concrete, longitudinal and transverse reinforcement.

Figure 3.5 Reinforcement of the concrete jacket (Spyrakos, 2004)

The concrete jackets are applied to columns (or to walls) for the following purposes:

- Increasing of the bearing capacity
- Increasing the flexural and/or shear strength
- Increasing the deformation capacity
- Improving the strength of deficient lap-slices

The thickness of the jacket should be enough for the placement of longitudinal and transverse reinforcement, with an adequate cover (EN 1998-3, 2005).

### 3.5.4.2 Retrofitting of Columns with Confinement

Retrofitting of columns with confinement is capable under the following circumstances:

- When increase of the ductility of the column is required
- When increase of the shear strength of the column is required
- When a maximum increase of $30 \%$ of the compression strength of the concrete is sufficient
- When the bond failure of the vertical reinforcement of the column at the area of overlap, is probable.

The confinement of reinforced concrete columns may be achieved by several techniques:

- Steel angle collars: they usually are steel sheets of thickness $1-2 \mathrm{~mm}$ or FRP sheets.
- Prestressed steel angle collars
- Spiral reinforcement made of steel sheet or FRP.
- Steel jacket made of steel sheets or FRP

The use of FRPs is widely used nowadays (Fardis et al.2003). Their properties, such as the high-strength-to-weight and the stiffness-to-weight ratios, the resistance to electrochemical corrosion and their easily handling make FRP material superior in comparison with other conventional materials in strengthening applications (Belarbi et al.2013).

Figure 3.6 Confinement using spiral reinforcement (Fardis et al.2003)

Figure 3.7 Confinement using steel sheets (Fardis et al.2003)

Figure 3.7 Complete FRP wrapping (Belarbi et al.2013)

No matter which technique is used, confinement has a significant impact to concrete behaviour. The ductility and the compressive strength of the confined element are extremely increased.

## CHAPTER 4

## Modelling of the structure using SAP 2000

### 4.1 SAP2000 Overview

SAP2000 is general-purpose civil engineering software. It is ideal for the analysis and design of any type of structural system. 2D, or 3D systems of complex or simple geometry may be modelled, analyzed and designed. The object-based modelling environment streamlines and simplifies the engineering process. Its features include integrated modelling templates, code-based loading assignments, design-optimization procedures, advanced analysis options, and customizable output reports (CSi Knowledge Base, 2013).

## Modelling

There is a broad range of modelling options. Model domain may be component, system, or global-level in scope, while encompassing sub-grade components and soil-structure interaction.

The members may be linear or curved, cables and post-tensioned tendons, link elements to model springs, dampers, isolators and the associated nonlinear and hysteretic behaviour. Moreover, modelling options are the frame elements, shells or multi-parametric shells, solid elements with isoparametric formulation, and nonlinear response. Section designer is available for the design of custom cross sections. The member properties are automatically calculated by the section designer once the user specifies the geometry of the section and the material composition. In addition, bi-axial interaction and moment-curvature diagrams are generated by the section designer.

Once the object-based model is created, it is automatically converted into a finite-element model by meshing the material domain with an efficient network of quadrilateral sub-elements.

It is an exceptional tool for modelling structural systems of any complexity and any project type (CSi Knowledge Base, 2013).

## Loading

Forces such as seismic, wind, vehicle, wave, and thermal may be automatically generated and assigned according to a suite of code-based guidelines. An unlimited number of load cases and combinations may be defined and enveloped by the user (CSi Knowledge Base, 2013).

## Analysis

SAP2000 is capable of any analysis type, ranging from simple static, linearelastic, to more complex dynamic and nonlinear-inelastic. Eigen analysis and Ritz analysis are also included in the options.

Material nonlinearity can be used to capture inelastic and limit-state behaviour. Plastic hinging may be specified in flexural members according to code-based standards or empirical data (CSi Knowledge Base, 2013).

Available for earthquake simulation are both static and dynamic methods. Modal, uniform, or user-defined lateral load patterns may be considered in nonlinear static pushover analysis. The plastic-hinging behaviour of slender elements, shear walls and steel plates may be determined. The formulation of demand capacity spectrum and the performance point calculations may be performed (CSi Knowledge Base, 2013).

Dynamic methods include:

- Response Spectrum (for likely maximum seismic response given pseudostatical acceleration vs structural period curve)
- Power-spectral-density and steady state (for fatigue behaviour with optional damping and complex-impedance properties)
- Time history analysis, which may follow modal or direct integration methods.

## Design and Output

Design is fully integrated with the analysis process. The results are enveloped, before the steel members are sized or the reinforced-concrete sections are designed. American, Canadian, and a variety of international standards (including EN 1998-2) are available (CSi Knowledge Base, 2013).

Output and display options are intuitive and practical. A few of the graphics available upon the conclusion of analysis are: finalized member design, deformed geometry per load combination or mode shape, moment, shear, and axial-force diagrams, section-cut response displays and animation of timedependent displacements. Reports for the presentation of images and data are automatically generated. (CSi Knowledge Base, 2013).

### 4.2 History and Description of the Structure

The reinforced concrete hotel was constructed in 1967 in Greece. The building was designed and constructed under the provision of the national codes of Members of Reinforced Concrete (1954) and of the Design Code for Earthquake Resistant structures (1959). The code of 1959 did not provide safety against earthquakes in comparison with the modern codes. Furthermore, the seismic actions according to the code of 1959 were significantly reduced in comparison with the ones supposed by the Eurocodes. The detailing of members and other particular rules were not included in the code for concrete members of 1954. In other words, the code was adequate for structures subjected only to vertical loads. As a result the majority of the buildings that were built before 1984 (when the basis of the modern codes was introduced) do not have a structural system to resist lateral loads in their both main horizontal axes. They are unsafe and vulnerable to earthquake motion. Inelastic behaviour, ductility and capacity design were completely unknown.

The hotel is in seismic zone $2\left(Z 2, a_{G R} / g=0.24\right)$. It is a 5 -storey reinforced concrete building with underground floor, ground floor (two levels), mezzanine
floor, approachable and non approachable roof. The total number of levels is 11. Its overall high is 27.53 m , including the non approachable roof, while the typical high of floors is 3.2 m (except the underground, ground and mezzanine floor). The reception of the hotel is at the North of the ground floor, while at the south of the ground floor there are shops. The floor plan for all the stories is common.

The floor plan of the building is polygonal, with dimensions $21.00 \mathrm{~m}, 14.85 \mathrm{~m}$, $12.7 \mathrm{~m}, 10.76 \mathrm{~m}$ as shown in the typical floor plan (figure 4.1).

Figure 4.1Typical Floor Plan
The structural system consists of columns, beams and slabs. Hence it is a frame system (in both X and Y axes), which according to EN 1998-1 (2004) is a structural system in which both the vertical and lateral loads are mainly resisted by spatial frames, whose total shear resistance at the building base exceeds $65 \%$ of the total shear resistance of the whole structure. In the perimeter of the underground floor, there are reinforced concrete shear walls. The underground floor is considered to be unshakable.

The slenderness $\lambda=L_{\text {max }} / L_{\text {min }}$ of the building in plan is $\lambda=21.00 / 11.7134=1.79<$ 4. However the plan configuration is not compact, since the area between the outline of the floor and a convex polygonal line enveloping the floor exceeds 5\% of the floor area for some of the set-backs (EN 1998-1, 2004). Hence the criteria for regularity in plan are not satisfied and a spatial model is required for the analysis of the building.

The building is regular in elevation, since setbacks do not exist at any floor level, the frames run from their foundations to the top of the building without interruptions and both the lateral stiffness and the mass of the building remain constant from the base to the top.

The building floor slabs including the approachable roof act as horizontal diagrams, collecting and transmitting the inertia forces to the vertical structural system and ensure that those systems act together in resisting the horizontal seismic action.

Figure 4.2 Building Model in SAP2000

Figure 4.3 Section A-A'
As shown in the $A-A^{\prime}$ section, the level $z=0 m$ is considered at the foundation level in order to be compatible with SAP2000 model, and not at the ground level.

Figure 4.8 Floor C ( $\mathbf{1 5 . 4 3 m}$ )

Figure 4.9 Floors D and E ( $\mathbf{1 8 . 6 3 m}$ and 21.83 m respectively)

### 4.3 Modelling of the Structure in SAP2000

The model is spatial. It consists of vertical and horizontal frame elements of orthogonal sections, representing the columns and the beams, respectively. It is mentioned that the beams are modelled as orthogonal sections, not as flanges. The slabs and the infill walls are not modelled, however not only their permanent and imposed loads, but also the diaphragmatic behaviour of the slabs, are taken into account. The shear walls in the perimeter of the underground level are modelled as extremely stiffed bracings. Soil-structure interaction is neglected. The foundation is considered fixed into the ground.

Figure 4.10 Model of the Building in SAP2000 (Extrude View)

Figure 4.11 Elevation View of the Building

### 4.3.1 Material Properties

The required information about the geometry of the structure and its elements is taken from the existing construction drawings. They were collected by the local town planning authorities having the owner's consent. However information about the reinforcement details is not available.

Assumptions are made about the mechanical properties of the materials, according to common practices of the time of the construction. In addition, it is assumed that full knowledge is succeeded; hence the confidence factor is taken equal to the unit $(C F=1)$.

Concrete B160 is used. It corresponds to strength class C12/15 according to EN1992-1 (2004). Its most important strength and deformation characteristics are:

Characteristic compressive cylinder strength of concrete at 28 days: $\mathrm{f}_{\mathrm{ck}}=12 \mathrm{MPa}$ Characteristic compressive cube strength of concrete at 28 days: $\mathrm{f}_{\mathrm{ck}, \mathrm{cube}}=15 \mathrm{MPa}$ Mean value of concrete cylinder compressive strength: $f_{c m}=20 \mathrm{MPa}\left(\mathrm{f}_{\mathrm{cm}}=\mathrm{f}_{\mathrm{ck}}+8\right)$

Mean value of axial tensile strength of concrete: $\mathrm{f}_{\mathrm{ctm}}=1.6 \mathrm{MPa}$

Young's modulus: $\mathrm{E}_{\mathrm{cm}}=27 \mathrm{GPa}$
Stain at maximum unconfined compressive strength, $\mathrm{f}^{\prime}:{ }_{c} \varepsilon_{c 1}=1,8 \%$

Ultimate unconfined stain capacity: $\varepsilon_{\mathrm{cu} 1}=3,5 \%$

The steel class of reinforcing bars is assumed STAHL 1, with minimum yield point $2200 \mathrm{~kg} / \mathrm{cm}^{2}$ and minimum tensile stress $3400-5000 \mathrm{~kg} / \mathrm{cm}^{2}$, according to the reinforced concrete code of 1954. The young modulus of the steel is assumed equal to $E_{s}=200$ GPA. STAHL 1 corresponds to S220. (Reinforcing Steel New Regulation, 2008)

The material properties are defined following the steps shown below:

Define $\Rightarrow$ Materials $\Rightarrow$ Add New Material

Figure 4.12 Definition of Material's Properties
The weight per unit volume of the concrete is defined $24 \mathrm{kN} / \mathrm{m}^{3}$ since the sections are considered lightly reinforced.

The Nonlinear Material Data, which is necessary for the inelastic analyses, is also defined for both materials, as shown in the figures 4.13 and 4.14.

Figure 4.13 Definition of Nonlinear Concrete Properties and Stress-Strain Curve
Nonlinear material behaviour may be taken into account through a directional material model, in which uncoupled stress-strain behaviour is modelled for one or more stress-strain components (CSi, 1995).

For each material an axial stress-strain curve that represents the direct (tensioncompression) stress-strain behaviour of the material along any material axis may be specified.

Concrete is an isotropic material. Thus the stress-strain curve represents the behaviour along each of the three axes $\sigma 11-\varepsilon 11, \sigma 22-\varepsilon 22, \sigma 33-\varepsilon 33$. The nonlinear stress-strain is the same in each direction (CSi, 1995).

Steel is a uniaxial material, thus the stress-strain curve represents the relationship between $\sigma 11$ and $\varepsilon 11$.

Figure 4.14 Definition of Nonlinear Steel Properties and Stress-Strain Curve

The hysteresis type defines the nonlinear stress-strain behaviour of the material when the load is reversed.

Kinematic hysteresis type is the default hysteresis model for all metal materials in the program, because it is based upon kinematic hardening behaviour that is commonly observed in metals. A significant amount of energy is dissipated by this model, thus it is appropriate for ductile materials (CSi, 1995).

Takeda model uses a degrading hysteretic loop. It is suitable for concrete or other brittle materials. Less energy is dissipated than the Kinematic model (CSi, 1995).

It is mentioned that the weight per unit volume of the concrete of the underground shear walls is not equal to the weight per unit volume of the concrete material shown in figure 4.12. The shear walls are modelled as bracings of $1 \mathrm{~m}^{2}$ sections, and the weight per unit volume is adjusted in order to result in the real self-weight of the shear walls, which dimensions are:

Width: 0.2 m
Height: $3 m$ (for the shear walls underneath the hotel)
Height: 4.06 m (for the shear walls underneath shops)
Their self-weight is:

Shear wall underneath hotel: $W=24 \cdot 0.2 \cdot 3=14.4 \mathrm{kN} / \mathrm{m}$

Shear wall underneath shops: $W=24 \cdot 0.2 \cdot 4.06=19.488 \mathrm{kN} / \mathrm{m}$

The weight per unit volume is adjusted so as the self-weight of the two bracings modelled in each frame is equal to the self-weight of the real existing shear walls.

Figure 4.15 Definition of Weight per Unit Volume of the Underground Shear Walls

### 4.3.2 Frame Sections

All the elements of the structure (except slabs) are designed using the section designer, where sections of arbitrary geometry and combination of materials may be designed. The geometric properties (areas, moments of inertia etc) are computed automatically. Furthermore, the reinforcing bars may be defined by the user (CSi, 1995).

The sections are modelled following the commands:

Define $\Rightarrow$ Section Properties $\Rightarrow$ Frame Properties $\Rightarrow$ Add New Property $\Rightarrow$ Other $\Rightarrow$ Section Designer

The "concrete column" (even though the element may not be a column) and "reinforcement to be checked" options must be selected as indicated in the figure 4.16. This option is used to specify whether the concrete member is to have its specified reinforcing checked, or new longitudinal reinforcing designed, when it is run through the concrete frame design postprocessor (CSi, 1995).

Figure 4.16 Selection of "Concrete Column" and "Reinforcement to be Checked" options

The steel and concrete characteristics that defined in 4.3.1 are selected. It is assumed that the concrete cover is 0.02 m .

In addition, all the frame sections are considered unconfined. The significance of the shear reinforcement was underestimated by the codes of 1954 and 1959. Thus, it is assumed that the long spacing between the stirrups do not provide confinement to the sections.

As known, the bending moments act at the bottom, in the mid-span of a beam and at the upper side of the section in the edge-spans. Thus the longitudinal reinforcing bars were placed at the bottom of the section in the mid-spans and at the upper side at the edge-spans of the beams.

Figure 4.17 Beam Longitudinal Reinforcement at the Bottom of the Section in the Mid-spans and at the Upper Side at the Edge-spans

Each beam is divided into 3 parts, one mid-span-longitudinal reinforcing bars at the bottom and two edge-spans-longitudinal reinforcing bars at the top of the section. It is assumed that each edge-span length is $25 \%$ and the mid-span length is $50 \%$ of the total length of the beam. The beam parts are connected through joints.

This is the best way to design the beams using the section designer. The section designer is useful because it is able to calculate the yield bending moment $\left(\mathrm{M}_{\mathrm{y}}\right)$ and curvature $\left(\Phi_{\mathrm{y}}\right)$ of the section (which is required for the calculation of secant stiffness-explained in 6.2) automatically.

Besides the main longitudinal reinforcement of the beams, $2 \Phi 10$ is considered at the top for both the mid-span and the edge-span.

Figure 4.18 a) B20x50 4Ф14 (mid-span) b) B20x50 4Ф14 (edge-span)

Figure 4.19 a) Column (C11A) b) Strip Foundation (in the perimeter of the foundation)

The columns in the foundation level of the building are connected to each other through connecting beams.

Strip foundation is modelled in the perimeter of the building at the foundation level. The underground shear walls are based on the strip foundation.

Once the definition of the frame sections is completed, the elements are designed using a spatial grid, which intersections are exactly at the positions of the joints of the building. It is mentioned that if the beams do not frame into the centre of a column or there are other eccentricities that should be taken into account, the "insertion point" command is used.

Frame elements are modelled as line elements connected at points (joints). However, all the structural members do have finite cross-sectional dimensions. As a result when two elements, for example a column and a beam are connected at a joint, there is some overlap of their cross sections. This overlapping is taken into account in SAP2000 by using the command "end length offsets". The dimensions of the members may be large and the length of overlap may be significant fraction of the total length of an element (CSi, 1995).

The end offsets are automatically calculated from the connectivity. It is considered that the reinforced concrete elements are connected monolithically, thus the "rigid zone factor" is taken equal to the unit. This indicates that the end offsets are fully rigid.

### 4.3.3 Stiffness- Property Modifiers

The stiffness of the elements has to be modified due to the cracking of the concrete sections. Unless a more accurate analysis of the cracked elements is performed and if linear analyses are applied and the behaviour factor q corresponds to the whole of the structure, the stiffness can be estimated as a percentage of the stiffness of the uncracked sections.

The values that are shown in the table can be used when no more accurate information is available.

Table 4.1 Stiffness of Cracked Sections (KANEPE, 2013)

| Structural Element | Stiffness |
| :--- | :--- |
| Internal Column | $0.8^{*}\left(\mathrm{E}_{\mathrm{c}} \mathrm{I}_{\mathrm{g}}\right)$ |
| Outer Column | $0.6^{*}\left(\mathrm{E}_{\mathrm{c}} \mathrm{I}_{\mathrm{g}}\right)$ |
| Shear Wall-non cracked | $0.7^{*}\left(\mathrm{E}_{\mathrm{c}} \mathrm{I}_{\mathrm{g}}\right)$ |
| Shear Wall, cracked | $0.5^{*}\left(\mathrm{E}_{\mathrm{c}} \mathrm{I}_{\mathrm{g}}\right)$ |
| Beam | $0.4^{*}\left(\mathrm{E}_{\mathrm{c}} \mathrm{I}_{\mathrm{g}}\right)$ |

Where: $\mathrm{E}_{\mathrm{c}} \mathrm{I}_{\mathrm{g}}$ is the stiffness of the uncracked section (elastic).
The values shown in the table 4.1 are used for the linear response spectrum analysis. The secant stiffness of the sections, which is explained in section 6.2 is used for the non linear analyses.

The stiffness may be modified by the option "Property Modifiers" in Sap 2000. Modification factors may be defined as frame section properties and assigned directly to frame objects, or they may be assigned to the frames by selecting them.

For example the commands:
Assign $\Rightarrow$ Frame $\Rightarrow$ Property Modifiers may be selected.
The factors that must be modified are the moment of inertia about 3 for the beams and the moment of inertia about 3 and about 2 for the columns, since the columns receive biaxial bending moment about those two local axes.

Figure 4.20 Stiffness Modification Factors

### 4.3.4 Loading

The codes "Rules for Actions on Structures FEK 171A/1946" and the "EN 1991-1-1:2002" (Eurocode 1 Actions on Structures) provide the load values listed in table 4.2.

Table 4.2 Actions on Structures

## Actions on the structure

| Self-weight (Permanent Loads) | $24 \mathrm{KN} / \mathrm{m}^{3}$ |
| :--- | :--- |
| Concrete self weight | $1.5 \mathrm{KN} / \mathrm{m}^{2}$ |
| Floors | $1.3 \mathrm{KN} / \mathrm{m}^{2}$ |
| Roof | $2.1 \mathrm{KN} / \mathrm{m}^{2}$ |
| Strecher Bond | $3.6 \mathrm{KN} / \mathrm{m}^{2}$ |
| Header Bond |  |
| Imposed Loads (Live Loads) | $2 \mathrm{KN} / \mathrm{m}^{2}$ |
| Floors | $3.5 \mathrm{KN} / \mathrm{m}^{2}$ |
| Stairs | $5 \mathrm{KN} / \mathrm{m}^{2}$ |
| Balconies | $5 \mathrm{KN} / \mathrm{m}^{2}$ |
| Shops | $2 \mathrm{KN} / \mathrm{m}^{2}$ |
| Approachable Roof | $1 \mathrm{KN} / \mathrm{m}^{2}$ |
| Non Approachable Roof |  |

As mentioned in 4.3 the slabs are not included in the model. Thus the slab load is distributed to the beams according to EKOS (2000) (Greek Code of Reinforced Concrete 2000). The slab is divided into areas through yield lines as shown in the figure 4.21. Each beam is considered receiving the load transmitted through its corresponding slab area. The division of the slab into areas is dependent on the corner supports of the slab. If in the two sides of a corner, the support is common (for example fixed supports) the division angle is $45^{\circ}$. If one of the sides is completely fixed and the other one is free edge, the division angle towards the fix support is $60^{\circ}$. For partially fixed supports the angle ranges between $45^{\circ}$ and $60^{\circ}$.

Figure 4.21 Slab Division into Areas for Loading Transfer to the Beams
In the figures 4.22-4.26, the division areas of the slabs are shown. In the tables 4.3-4.9, the total permanent load (due to the slabs and the walls) and the total imposed load (due to the slabs) transmitted to the beams is presented. Detailed calculations are cited in the appendix B.

Prior the application of the loads to the model, the load patterns should be defined. The load patterns are:

Dead load: it is the self weight of the elements-calculated automatically by the SAP2000.

Dead load (slabs-permanent load): it is the permanent load of the slabs (including the infill walls) as calculated above. Since its calculation, as shown in the appendix B, takes into account the self weight of the slab, the self weight multiplier should be set equal to zero. Otherwise the self weight will be added twice, leading to obviously irrational results.

Imposed load and Imposed load (shops): As shown in the table 4.2 the live loads for shops is greater than the live loads for common floors, thus two separate load patterns are defined.

Balcony Moment: The balconies are not included in the model. However the bending moment that causes torsion to the beams they are attached, is taken into account. The calculation of the bending moment due to the balconies is:
(Permanent Load of the Balcony $(\mathrm{kN} / \mathrm{m})+0.3 \cdot$ Imposed Load of the Balcony $(\mathrm{kN} / \mathrm{m})$ ). -Beam Length ( $m$ ) Balcony width ( $m$ )

Figure 4.27 Load Patterns Definition

The loads are assigned to the beams, following the commands:

Assign $\Rightarrow$ Frame Loads $\Rightarrow$ Distributed

Figure 4.28 Loads Assignment to the Beams
The load patterns and the coordinate system are selected. The direction of all loads is set to gravity (except the balcony moment which is set about the appropriate local axis). The value of the uniform load is typed in the field "Load", as shown in figure 4.28.

### 4.3.5 Diaphragms

The diaphragmatic behaviour of the slab is considered. The slabs are flexible towards the perpendicular to their plane direction (z-direction), however inplane they are considered to act as non-deformed plates (their deformation is low enough to be neglected). As a result the deformations of the in-plane (plane xy ) joints of the slabs are not independent. They are constrained by the three degrees of freedom of the diaphragm, which is able to move as a solid body in the xy plane (Katsikadelis, 2012).

In SAP2000 a diaphragm constraint may be used to represent the behaviour of the slab, since it causes all of its constrained joints to move together as a planar
diaphragm that is rigid against membrane deformation, but do not affect out-ofplane (plate) deformation.

It is very useful in the lateral (horizontal) dynamic analysis of buildings, as it results in a significant reduction in the size of the eigenvalue problem to be solved CSi, 1995).

Figure 4.29 Use of Diaphragm Constraint to Model a Rigid Floor Slab (CSi, 1995)
The diaphragm constraint is applied in SAP 2000 through the following steps, since all the joints of the desirable level are selected.

Assign $\Rightarrow$ Joint $\Rightarrow$ Constraints $\Rightarrow$ Diaphragm

Figure 4.30 Diaphragm Constraints Definition
The Z-axis constrained should be selected, since it defines a perpendicular to the Z-axis diaphragm (CSi, 1997).

## Chapter 5

## Modal Response Spectrum Analysis of the Existing Structure

### 5.1 Modal Analysis

A modal analysis is defined by creating a load case and setting its type to modal. Modal analysis is always linear. The values of the stiffness of the structure elements are taken from table 4.1, which is appropriate for linear analyses.

The Eigen Vectors type of modes and stiffness from zero initial conditionsunstressed state are chosen. The number of modes is set high enough, so all modes with effective modal mass greater than $5 \%$ of the total mass are taken into account as suggested in EN 1998-1 (2004). Thus the number of modes is set to: 170

The mass source has to be defined; otherwise the program is not able to solve the generalized eigenvalue problem:
$\left[K-\Omega^{2} M\right] \Phi=0$
(31) (CSi, 1995)

The mass is defined from elements, additional masses and loads. By selecting this option, the mass from the elements of the structure and the mass from permanent and imposed loads (due to slabs and infill walls that are not modelled) are taken into account (there are no additional masses). As a result the total mass of the structure is considered for the modal analysis. The loads are combined through the combination $\mathrm{G}+\Psi_{2} \mathrm{Q}$, where $\Psi_{2}$ is the coefficient for imposed (live) loads.
$\Psi_{2}=0.3$ for usual residences (Category A)
$\Psi_{2}=0.6$ for shops (Category D) (EN 1990, (2002) Greek National Annex)

Define Mass Source

Figure 5.1 Mass Sources Definition
The modal participating mass ratios of the first 5 and the last 5 modes are presented in the following table:

Table 5.1 Modal Analysis Results: Modal Participating Mass Ratios of the first 5 and the last five modes of the structure

| OutputCase | StepType | StepNum | Period | UX | UY | UZ | RX | RY | RZ |
| :--- | :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

The deformed shapes of the first 3 modes are presented in the figures 5.2 to 5.4 :

Figure 5.2 Deformed Shape of Mode 1: T1=1.627sec. Translational along $X$ axis

Figure 5.3 Deformed Shape of Mode 2: T2= 1.405sec. Translational along Y axis

Figure 5.4 Deformed Shape of Mode 3: T3= 1.142sec. Rotational about Z axis

### 5.2 Response Spectrum Analysis

The response spectrum function is defined in SAP 2000 by the commands:

Define $\Rightarrow$ Functions $\Rightarrow$ Response Spectrum $\Rightarrow$ (Choose Function Type to Add) $\Rightarrow$ EuroCode 82004

Subsequently the required parameters are defined:

Horizontal Ground Acceleration: $0.24 \mathrm{a}_{\mathrm{g}} / \mathrm{g}$ (where $\left.\mathrm{a}_{\mathrm{g}}=\mathrm{a}_{\mathrm{gr}} \gamma_{\mathrm{I}}\right)\left(\mathrm{Y}_{\mathrm{I}}=1\right)$

## Spectrum Type: 1

## Ground Type: B

Soil Factor, S: 1.2

Tb:0.15 sec

Tc: 0.5 sec

Td:2.5 sec

## $\beta: 0.2$

Behaviour factor q: 3.5

Figure 5.5 Response Spectrum Function Definition

The load case for the vertical static loads (G+0.3Q) is defined. The initial conditions are set to zero and the linear analysis type is chosen. The loads applied are shown in the figure 5.6.

Figure 5.6 Vertical Loads-Case Definition
The earthquake load cases along the axis $X$ and $Y$ are defined.

Figure 5.7 Definition of Load Case of Seismic Action Imposed to the Building along the $X$ axis.

The vertical and seismic loads are combined through the commands: Define $\Rightarrow$ Load Combinations $\Rightarrow$ Add New Combo

Figure 5.7 Definition of The combination of the Vertical Loads+Ex+0.3Ey
The response spectrum analyses are performed for the load combinations:
$G+0.3 Q+E x+0.3 E y, G+0.3 Q+E x-0.3 E y, G+0.3 Q-E x+0.3 E y, G+0.3 Q+E x-0.3 E y$, $\mathrm{G}+0.3 \mathrm{Q}+0.3 \mathrm{Ex}+\mathrm{Ey}, \mathrm{G}+0.3 \mathrm{Q}+0.3 \mathrm{Ex}-\mathrm{Ey}, \mathrm{G}+0.3 \mathrm{Q}-0.3 \mathrm{Ex}+\mathrm{Ey}, \mathrm{G}+0.3 \mathrm{Q}-0.3 \mathrm{Ex}-\mathrm{Ey}$, G+0.3Q+SRSS (Ex,Ey)

Where $\mathrm{G}+0.3 \mathrm{Q}$ is the combination of the vertical loads of the structure, taken into account for dynamic analyses according to EN 1998 (2004)

### 5.3 Modal Response Spectrum Analysis Results

The maximum displacements and the maximum forces along each axis, for each floor level, are presented in the following tables. The maximum due to the SRSS combination is common along both X and Y axes.

Table 5.2 Maximum Column Forces per Floor Level for Load Combinations: $\mathbf{G}+0.3 Q+E x+0.3 E y, \quad G+0.3 Q+E x-0.3 E y, \quad G+0.3 Q-E x+0.3 E y, \quad G+0.3 Q+E x-0.3 E y$, G+0.3Q+SRSS (Ex,Ey)

Table 5.3 Maximum Column Forces per Floor Level for Load Combinations: $\mathbf{G}+0.3 Q+0.3 E x+E y, \quad G+0.3 Q+0.3 E x-E y, \quad G+0.3 Q-0.3 E x+E y, \quad G+0.3 Q-0.3 E x-E y$, G+0.3Q+SRSS (Ex,Ey)

| Column Forces (Earthquake along main axis $Y$ and SRSS combination) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Floor <br> Level | P (KN) | V2 (KN) | V3 (KN) | M2 <br> (KNm) | $\begin{gathered} \text { M3 } \\ (\mathrm{KNm}) \end{gathered}$ |
| Ground Floor | -1350.484 | -187.63 | -181.631 | -197.5393 | 145.1213 |
| Mezzanine Floor | -1128.76 | 90.843 | -149.974 | -154.1498 | 100.2469 |
| A | -1143.121 | 123.363 | -148.432 | 167.8805 | 128.1647 |
| B | -711.273 | -91.415 | -111.993 | -143.1798 | -116.5706 |
| C | -496.56 | -84.867 | -102.469 | 133.6989 | 111.5601 |
| D | -309.017 | 51.895 | -78.276 | 103.2685 | -71.3941 |
| E | -144.086 | 76.19 | -55.757 | 79.8612 | -110.8466 |

The magnitudes that share common values for a specific floor level, no matter which one is the main analysis axis, show that their maximum value is obtained by the SRSS combination.

For both the main directions of the earthquake, the maximum forces act in the ground floor level. In addition, it is observed that the same frames face the maximum forces no matter which one is the main direction of the earthquake.

Figure 5.8 Column Frames Facing the Maximum Values of Magnitudes

The columns which face the maximum $\mathrm{P}, \mathrm{V} 2, \mathrm{~V} 3, \mathrm{M} 2, \mathrm{M} 3$ are shown in the figure 5.8. They are the columns $\mathrm{C} 4, \mathrm{C} 3, \mathrm{C} 1$ and C 20 respectively. The maximum $\mathrm{V} 2, \mathrm{~V} 3, \mathrm{M} 3$ are observed in short columns.

Table 5.4 Maximum displacements U1,U2,U3 per floor level due to earthquake along the $X$ axis $G+0.3 Q+E x+0.3 E y, G+0.3 Q-E x+0.3 E y, G+0.3 Q E x-0.3 E y, G+0.3 Q$-Ex$0.3 E y$ and $G+0.3 Q+S R S S$ (Ex, Ey)

| Ground Floor <br> (Hotel) | 4 | -0.00014 | 0.00043 | -0.00538 |

The displacements U1, U2, U3 corresponds to the global axes $X, Y, Z$, of the SAP2000 model, respectively.

The common displacements between the two tables are the result of the SRSS combination of the seismic forces.

The results show that the upper floor levels face larger displacements than the lower floor levels.

The U3 displacement is always negative as expected.
The ground floor levels may be considered unshakable.

The larger displacement of the structure is observed at the approachable roof level ( 25.03 m ) along the U2 direction. It is -0.0891 m at the joint 179 as shown in the figure 5.9. It is the result of the SRSS combination of the seismic forces.

 observed at the approachable roof level ( 25.03 m )

The larger displacement of the structure along the U 1 axis is -0.0758 m at the approachable roof (25.03m). It is the result of the G+0.3Q+Ex+0.3Ey combination of forces. It is observed at the joints shown in the figure 5.10

Figure 5.10 Joints that maximum displacement ( -0.0758 m ) along the U 1 axis is observed at the approachable roof level (25.03m)

## Chapter 6

## Nonlinear Static (Pushover) Analysis of the Existing Structure

According to KANEPE (2013), the nonlinear parameters of the materials should be taken into account when nonlinear analyses are performed. They are defined in section 4.3.1. The force-displacement behaviour of all components shall be explicitly included in the model using full backbone curves that include strength degradation and residual strength if any. They are assigned to the model through the plastic hinges.

The model is subjected to lateral loads. Use of more than one lateral load pattern is intended to bound the range of actions that may occur during actual dynamic response. Thus the uniform load distribution and the distribution of load patterns based on mode shapes are used. The loads are monotonically increased until the target displacement is reached, or the building is collapsed. The capacity curve is produced by the procedure described in 2.3.2.

The performance check for the whole building takes place, based on the deformations of each one of the elements, during the segmental increase of the lateral loads.

### 6.1 Limitations on Use of the Nonlinear Static Analysis-Higher Mode Participation Check

As mentioned in 2.3.2.1, static pushover analysis shall be permitted for structures that higher mode effects are not significant.

Two modal response spectrum analyses, suggested by KANEPE (2013) are performed. In the first the $90 \%$ of mass participation is captured and in the second only the fundamental mode in each direction is taken into account. The shear force in columns of all stories is compared, as indicated in the tables 6.1 and 6.2.

Table 6.1 Higher mode participation check for earthquake imposed along the $X$ axis.

| Earthquake imposed along X axis |  |  |  |
| :---: | :---: | :---: | :---: |
| Floor Level | Shear Force <br> (KN)- <br> Capturing <br> the 90\% of <br> mass <br> participation | Shear Force <br> (KN)- <br> Fundamental <br> mode (X <br> axis) | Variation <br> (\%) |
| Ground | 986.40 | 767.92 | 128.45 |
| Floor | 527.23 | 436.57 | 120.77 |
| A | 466.98 | 379.99 | 122.89 |
| B | 389.92 | 301.71 | 129.24 |
| C | 297.92 | 228.65 | 130.29 |
| D | 186.34 | 142.30 | 130.95 |
| E |  |  |  |

Table 6.2 Higher mode participation check for earthquake imposed along the $\mathbf{Y}$ axis

| Earthquake imposed along Y axis |  |  |  |
| :---: | :---: | :---: | :---: |
| Floor Level | Shear Force <br> (KN)- <br> Capturing <br> the 90\% of <br> mass <br> participation | Shear Force <br> (KN)- <br> Fundamental <br> mode (Y <br> axis) | Variation <br> (\%) |
| Ground | 961.59 | 841.33 | 114.29 |
| Floor | 573.73 | 548.95 | 104.51 |
| A | 504.70 | 485.13 | 104.03 |
| B | 427.92 | 388.66 | 110.10 |
| C | 334.71 | 262.99 | 127.27 |
| D | 229.43 | 175.82 | 130.49 |
| E |  |  |  |

It is concluded that the higher mode effects are not significant, since the shear in any story resulting from the modal response spectrum analysis, considering modes required to obtain $90 \%$ of mass participation, does not exceed $130 \%$ of the corresponding story shear, considering only the fundamental mode response in either direction. Thus the non linear static analysis is permitted.

### 6.2 Secant Stiffness

For the nonlinear analyses, the secant stiffness of each element of the structure should be taken into account.

If the verification is carried out in terms of deformations, deformation demands should be obtained from an analysis of a structural model in which the stiffness of each element is taken to be equal to the mean value of $K=\frac{M_{y} \cdot L_{v}}{3 \cdot \Theta_{y}}$ at the two ends of the element. (For columns where the reinforcement at the bottom and at the top is usually the same, the calculation of the mean of the secant stiffness of the two ends is adequate. However in beams where the upper and the bottom reinforcement at the edge differ, the secant stiffness should be calculated for the upper and bottom of each edge. As a result the secant stiffness of the beam element is the mean of the four values calculated-two at each end). In this calculation the shear span at the end section, $L_{v}$, may be taken to be equal to the half of the element clear length (EN 1998-3, 2005). However for beams connected with a vertical element only at one end, the $L_{v}$ may be taken to be equal to the total clear length of the beam. For shear walls $L_{v}$ may be modified depending on the floor level- it may be taken equal to the half of the distance between the lower section of each floor and the top of the shear wall in the building (KANEPE, 2013). $M_{y}$ is the yield moment and $\theta_{y}$ is the yield rotation of the end section of the element.
$M_{y}$ is calculated automatically by the section designer of SAP2000. The program computes the moment-curvature diagram of each section, by analyzing the sections. The stress-strain relations of the materials, taking into account their nonlinear properties, defined in 4.3.1 are used for this purpose. The momentcurvature diagram is automatically transformed into a bi-linear diagram
according to Caltrans Seismic Design Criteria. The values of the bi-linear diagram are referred to the section designer as $M_{p}$ and Phi-yield (idealized), thus those are used for the calculation of the secant stiffness. The behaviour of each section should be taken into account under the act of a representative axial force (for the columns). Thus a linear response spectrum analysis under the seismic combination of loads $(G+0.3 Q)$ is performed to provide the axial loads of the columns, used for the calculation of yield moment of the section. The behaviour of the beams which is different between the upper and bottom side of each end, due to asymmetry between the upper and bottom reinforcing steel, is taken into account through the angle option, available in section designer (Angle (Deg) $=0$ for tension in the bottom reinforcement, and Angle (Deg)=180 for tension in the upper reinforcement).

Figure 6.1 Moment-Curvature diagram of column C11 at the A floor level.
$\theta_{y}$ is computed using a Microsoft Excel Spreadsheet, by the equations provided in (EN 1998-3, 2005) and explained 2.4.6. As mentioned earlier the equations are:

For beams and columns:

$$
\theta_{y}=\varphi_{y} \cdot \frac{L v+a_{v} \cdot z}{3}+0.0013 \cdot\left(1+1.5 \frac{h}{L v}\right)+0.13 \cdot \varphi_{y} \frac{d_{b} \cdot f_{y}}{\sqrt{f_{c}}}
$$

(32) (EN 1998-3, 2005)

And for walls of rectangular, T- barbelled section:

$$
\begin{equation*}
\theta_{y}=\varphi_{y} \cdot \frac{L_{v}+a_{v} \cdot z}{3}+0.002 \cdot\left(1-0.125 \cdot \frac{L_{v}}{h}\right)+0.13 \cdot \varphi_{y} \cdot \frac{d_{b} \cdot f_{y}}{\sqrt{f_{c}}} \tag{33}
\end{equation*}
$$

$\Phi_{\mathrm{y}}$ is taken by section designer of SAP2000 as described above.
The stiffness modification should be applied to the SAP 2000 model by the commands described in 4.3.3. The percentage of the section that is effective and is able to sustain loads is represented by the ratio $\frac{K_{\text {eff }}}{K_{e l}}$ where $K_{\text {eff }}$ is the secant stiffness and $K_{e l}$ is the elastic stiffness of the section $K_{e l}=E \cdot I$.

The properties that must be modified, as mentioned in the 4.3 .3 are the moment of inertia about 3 for the beams and the moment of inertia about 3 and about 2 for the columns, since the columns receive biaxial bending moment about those two local axes.

The maximum and minimum values of $\frac{K_{e f f}}{K_{e l}}$ for columns are 0.329 and 0.119, respectively. The average value is 0.230 .

The maximum and minimum values of $\frac{K_{\text {eff }}}{K_{e l}}$ for beams are 0.217 and 0.045, respectively. The average value is 0.130 .

An example of the calculations is shown in the tables 6.3 and 6.4:

Table 6.3 Secant Stiffness of Beams

### 6.3 Plastic Hinges

It is considered that the plastic deformation is concentrated in the plastic hinges at the two edges of each column and beam. In addition here a plastic hinge in the middle of each beam is defined in order to research its behaviour.

The hinges are applied to each element by the commands:

Assign $\Rightarrow$ Frame $=$ Hinges
The hinge properties-backbone curve is taken from FEMA 356 tables which are included in SAP2000. The automatic calculation of the properties of each hinge is based on the section properties of the elements (dimensions, materials, reinforcing steel), which have been designed in section designer.

For the columns, the degree of freedom is set to P-M2-M3, because the axial force and the biaxial bending moment influence the element deformation. For the beams the degree of freedom is set to M3.

It is assumed that the transverse reinforcement does not provide confinement. It is assumed that the FEMA 356 criterion (a component is conforming if, within the flexural plastic hinge region, hoops are spaced at $\leq \mathrm{of} \mathrm{d} / 3$, and if, for components of moderate and high ductility demand, the strength provided by the hoops (Vs) is at least three-fourths of the design shear) is not satisfied.

Auto Hinge Assignment Data

Figure 6.2 Auto Hinge Assignment Data for Concrete Columns

Auto Hinge Assignment Data

Figure 6.3 Auto Hinge Assignment Data for Concrete Beams

Subsequently the FEMA 356 tables, which define the backbone curve of the hinges, for concrete beams and concrete columns are shown.

Figure 6.4 Hinge Backbone Curve according to FEMA 356 (2000)

Figure 6.6 Modelling Parameters and Numerical Acceptance Criteria for Nonlinear Procedures-Reinforced Concrete Columns (FEMA 356, 2000)

### 6.4 Nonlinear Static (Pushover) Analysis

The pushover analysis is performed in two phases. Firstly, the load case of the vertical loads $(G+0.3 Q)$ is set to nonlinear and it is run from zero initial conditions- "start from unstressed state". Secondly the load case of the lateral loads is set to analysis type: Nonlinear and it is set to run from the end of the nonlinear case of the vertical loads, by the command: "Continue from state at end of nonlinear case": G+0.3Q.

The lateral loads distributions used are the uniform load distribution and the distribution based on the mode shapes. (When the latter is chosen, a modal analysis is run before the vertical and lateral loads application to the structure). The load type $\Rightarrow$ Accel is set for uniform distribution of loads and the load type $\Rightarrow$ Mode is set for modal pattern. If modal pattern is selected the distribution of lateral loads is based on the mode shape of the fundamental mode of the corresponding direction (Mode 1 is set for X axis and Mode 2 for Y axis).

It is interesting to note the modal analysis results, since the secant stiffness of the elements is used.

In the following table the modal mass participation ratios and the fundamental periods of the first 5 modes are shown.

Table 6.5 Modal Participating Mass Ratios of the first 5 Modes

| OutputCase | StepType | StepNum | Period | UX | UY | UZ | RX | RY | RZ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Text | Text | Unitless | Sec | Unitless | Unitless | Unitless | Unitless | Unitless | Unitless |
| MODAL | Mode | 1 | 2.639646 | 0.32636 | 0.08261 | 4.702E-08 | 0.06237 | 0.19121 | 0.09604 |
| MODAL | Mode | 2 | 2.368858 | 0.05254 | 0.42026 | 0.000006131 | 0.31761 | 0.03047 | 0.03167 |
| MODAL | Mode | 3 | 1.942065 | 0.13775 | 0.0017 | 0.000001648 | 0.00139 | 0.0805 | 0.35319 |
| MODAL | Mode | 4 | 0.870279 | 0.03751 | 0.01383 | 0.00000785 | 0.00992 | 0.02946 | 0.00918 |
| MODAL | Mode | 5 | 0.797585 | 0.00962 | 0.0556 | 0.000005013 | 0.0399 | 0.0068 | 0.00381 |

By comparing the results of the modal analysis using the secant stiffness of the elements and the modal analysis using the stiffness that is proposed by the table 4.1 (KANEPE, 2013), it is shown that even if the participating mass ratios are not significantly different, the periods of the first three modes are
approximately 1 sec higher when secant stiffness is used, resulting to a much more flexible structure.

Figure 6.7 Definition of the Load Case of a Nonlinear Static Analysis. Uniform Distribution of Lateral Loads along the $+\mathbf{Y}$ axis.

The control node is the joint 130 of the structure, since it is the closer to the center of mass of the approachable roof (25.03m).

Eight nonlinear static analyses are performed (4 for each load distribution along the axes $+X,-X,+Y,-Y)$.

Load Application Control for Nonlinear Static Analysis

Figure 6.8 Load Application Control for Nonlinear Static Analysis

The displacement control option is set if the desirable displacement of the control node is known, but how much load is required is unknown. Using displacement control is not the same thing as applying displacement loading on the structure. Displacement control is simply used to measure the displacement at one point that results from the applied loads, and to adjust the magnitude of the loading in an attempt to reach a certain measured displacement value. The overall displaced shape of the structure will be different for different load patterns, even if the same displacement is controlled (CSi, 1995).

Results Saved for Nonlinear Static Load Cases

Figure 6.9 The results are saved in multiple states.

### 6.5 Results of Nonlinear Static (Pushover) Analysis

The results of the pushover analyses include the pushover curves and the capacity spectrums in ADRS format. In addition the deformed shape of the structure and tables showing the hinge results at the performance point are presented.

In the ADRS format, the red line represents the elastic response spectrum of Eurocode 8 (reduced according to the ATC-40 methodology), the green line represents the capacity curve of the equivalent single degree of freedom system and the cross-section of the green with the orange line indicates the performance point.

Nonlinear Static Analysis along -X Axis (Uniform Distribution of Lateral Loads)

a

b

Figure 6.10 a) Pushover Curve (Uniform Distribution of Lateral Loads along -X Axis) b) ATC-40 Capacity Spectrum-ADRS (Uniform Distribution of Lateral Loads along -X Axis)

Performance Point: $\mathrm{V}=1625.041 \mathrm{KN}, \mathrm{D}=0.161 \mathrm{~m}, \mathrm{~S}_{\mathrm{a}}=0.105 \mathrm{~g}, \mathrm{~S}_{\mathrm{d}}=0.148 \mathrm{~m}$

Figure 6.11 Deformed Shape of the Structure at Performance Point- Step 91-92 (Uniform Distribution of Lateral Loads along -X Axis)

Table 6.6 Hinges Limit State Results at Performance Point (Step 91-92)

| Step | Displacement m | BaseForce KN | AtoB | BtoIO | IOtoLS | StoCP | CPtoC | CtoD | DtoE | BeyondE | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 90 | 0.160247 | 1643.613 | 924 | 97 | 39 | 34 | 2 | 1 | 1 | 7 | 1105 |
| 91 | 0.160249 | 1622.208 | 924 | 97 | 39 | 34 | 2 | 1 | 1 | 7 | 1105 |
| 92 | 0.162503 | 1635.329 | 924 | 96 | 39 | 34 | 2 | 1 | 2 | 7 | 1105 |
| 93 | 0.162505 | 1620.953 | 923 | 95 | 41 | 34 | 2 | 1 | 1 | 8 | 1105 |
| 94 | 0.164674 | 1632.083 | 921 | 94 | 43 | 35 | 2 | 1 | 1 | 8 | 1105 |

It is shown that 46 hinges exceed the life safety limit state in total. 34 hinges are between the limit states life safety and collapse prevention, 5 face significant strength degradation since they exceed the collapse prevention limit state and 7 hinges lose even their residual strength (Beyond E).

The hinges beyond $E$ are found in beams in the West of the floor level $A$ and in the North-West and centre of the floor level B.

The column C11 faces significant damage since two hinges exceed the collapse prevention limit state and one hinge exceeds the collapse limit state, in floor levels C,D and E.

The column C18 faces significant problems since there is one hinge exceeding the limit state life safety in floor level E .

Nonlinear static analysis along +X Axis (Uniform Distribution of Lateral Loads)

a

b

Figure 6.12 a) Pushover Curve (Uniform Distribution of Lateral Loads along $+X$ Axis) b) ATC-40 Capacity Spectrum-ADRS (Uniform Distribution of Lateral Loads along $+\mathbf{X}$ Axis)

Performance Point: Not found

Figure 6.13 Deformed Shape of the Structure at Maximum Step of the Analysis (Uniform Distribution of Lateral Loads along +X Axis)

Table 6.7 Hinges Limit State Results

The performance point is not obtained by the analysis, showing that the capacity of the building is inadequate. The capacity is lower than the seismic
demand. The pushover analysis cannot displace the structure beyond 0.21 m due to the total strength loss of many hinges.

At the maximum step the analysis reached, the displacement of the control node is 0.21 m the base force 1161.494 KN and totally 56 hinges exceed the life safety limit state. 9 hinges have no residual strength (Beyond E), 2 exceed the collapse prevention limit state and 44 are between life safety and collapse prevention limit state.

Only two of the hinges that exceed life safety limit state are found in columns (C11 and C18). However the results indicate that the building faces severe damages to many elements. The most extreme damages (hinges beyond E ), are in beams in the South-West, West, and in the centre of the building in the floor levels $A$ and $B$.

Nonlinear Static (Pushover) Analysis (Uniform Distribution of Lateral Loads along +Y Axis)

Figure 6.14 a) Pushover Curve (Uniform Distribution of Lateral Loads along +Y Axis) b) ATC-40 Capacity Spectrum-ADRS (Uniform Distribution of Lateral Loads along +Y Axis)

Performance Point: $V=1122.347 \mathrm{KN}, \mathrm{D}=-0.240 \mathrm{~m}, \mathrm{~S}_{\mathrm{a}}=0.080 \mathrm{~g}, \mathrm{~S}_{\mathrm{d}}=0.158 \mathrm{~m}$

Figure 6.15 Deformed Shape of the Structure at Performance Point-Step 82 (Uniform Distribution of Lateral Loads along +Y Axis)

Table 6.8 Hinges Limit State Results at Performance Point (Step 82)

| Step | Displacement m | BaseForce KN | AtoB | BtoIO | IOtoLS | LStoCP | CPtoC | CtoD | DtoE | BeyondE | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 80 | -0.23907 | 1128.462 | 881 | 95 | 59 | 63 | 0 | 0 | 4 | 3 | 1105 |
| 81 | -0.239073 | 1116.047 | 881 | 95 | 59 | 63 | 0 | 0 | 4 | 3 | 1105 |
| 82 | -0.24048 | 1122.455 | 881 | 95 | 59 | 63 | 0 | 1 | 3 | 4 | 1105 |
| 83 | -0.240483 | 1118.072 | 881 | 95 | 59 | 63 | 0 | 0 | 3 | 4 | 1105 |
| 84 | -0.243945 | 1130.918 | 881 | 94 | 59 | 63 | 0 | 0 | 4 | 4 | 1105 |

At the performance point (step 82), 71 hinges exceed the life safety limit state. The 4 hinges beyond $E$, indicating components having no residual strength, are found in beams in the South-East of the building at the floor levels B and C.

One hinge in column C11 exceeds the collapse limit state. It faces significant strength degradation.

Nonlinear Static Analysis along -Y Axis (Uniform Distribution of Lateral Loads)

a

b

Figure 6.16 a) Pushover Curve (Uniform Distribution of Lateral Loads along -Y Axis) b) ATC-40 Capacity Spectrum-ADRS (Uniform Distribution of Lateral Loads along -Y Axis)

Performance Point: $V=1734.622 \mathrm{KN}, \mathrm{D}=0.148 \mathrm{~m}, \mathrm{~S}_{\mathrm{a}}=0.122 \mathrm{~g}, \mathrm{~S}_{\mathrm{d}}=0.146 \mathrm{~m}$

Figure 6.17 Deformed Shape of the Structure at Performance Point-Step 84 (Uniform Distribution of Lateral Loads along -Y Axis)

Table 6.9 Hinges Limit States at Performance Point (Step 84)

| Step | Displacement m | BaseForce KN | AtoB | BtoIO IOtoLS LStoCP |  |  | CPtoC CtoD |  | DtoE BeyondE |  | Total <br> 1105 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 82 | 0.144424 | 1721.425 | 917 | 110 | 55 | 21 | 0 | 1 | 0 | 1 |  |
| 83 | 0.147516 | 1732.874 | 915 | 112 | 53 | 23 | 0 | 1 | 0 | 1 | 1105 |
| 84 | 0.149416 | 1739.577 | 915 | 111 | 53 | 24 | 1 | 1 | 0 | 1 | 1105 |
| 85 | 0.152764 | 1751.2 | 914 | 107 | 55 | 26 | 0 | 1 | 1 | 1 | 1105 |
| 86 | 0.152766 | 1724.665 | 913 | 105 | 53 | 31 | 0 | 1 | 0 | 2 | 1105 |

At the performance point (step 84), 27 hinges exceed the life safety limit state, showing that the pushover analysis with uniform distribution of loads along the $-Y$ axis caused lesser damages to the structure, than the other analyses of uniform distribution of lateral loads. One hinge exceeds limit state E. It is in the center of the building in the floor level A .

Hinges in columns C18 and C11 exceed limit states of collapse prevention and collapse, respectively. They face severe damages and strength degradation.

Nonlinear Static Analysis along +X Axis (Modal Distribution of Lateral Loads)

a

b

Figure 6.18 a) Pushover Curve (Modal Distribution of Lateral Loads along +X Axis) b) ATC-40 Capacity Spectrum-ADRS (Modal Distribution of Lateral Loads along +X Axis)

Performance Point: $\mathrm{V}=811.006, \mathrm{D}=0.181 \mathrm{~m}, \mathrm{~S}_{\mathrm{a}}=0.045 \mathrm{~g}, \mathrm{~S}_{\mathrm{d}}=0.165 \mathrm{~m}$

Figure 6.19 Deformed Shape of the Structure at Performance Point-Step 89 (Modal Distribution of Lateral Loads along +X Axis)

Table 6.10 Hinges Limit State Results at Performance Point (Step 89)

| Step | Displaceme <br> m | seForc KN | toB | BtoIO | IOtoLS | LStoCP | CPtoC | CtoD | DtoE | BeyondE | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 87 | 0.178721 | 806.886 | 901 | 110 | 40 | 42 | 0 | 1 | 2 | 9 | 1105 |
| 88 | 0.180871 | 810.972 | 898 | 111 | 40 | 44 | 0 | 1 | 2 | 9 | 1105 |
| 89 | 0.182928 | 814.841 | 898 | 110 | 41 | 43 | 0 | 1 | 3 | 9 | 1105 |
| 90 | 0.18293 | 808.104 | 898 | 110 | 41 | 43 | 0 | 1 | 1 | 11 | 1105 |
| 91 | 0.152823 | 692.86 | 898 | 110 | 41 | 43 | 0 | 1 | 1 | 11 | 1105 |

At the performance point there are 56 hinges that exceed the limit state of life safety. The most severe damages (hinges beyond E) are located in beams in the West of the building at A and B floor levels.

a

b

Figure 6.20 a) Pushover Curve (Modal Distribution of Lateral Loads along -X Axis) b) ATC-40 Capacity Spectrum-ADRS (Modal Distribution of Lateral Loads along -X Axis)

Performance Point: Not found

Figure 6.21 Deformed Shape of the Structure at Maximum Step of the Analysis (Modal Distribution of Lateral Loads along -X Axis)

Table 6.11 Hinges Limit State Results

| Step | Displacement <br> m | BaseForce KN | AtoB | BtoIO | IOtoLS | LStoCP | CPtoC | CtoD | DtoE | BeyondE | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 92 | -0.146768 | 440.759 | 926 | 108 | 34 | 32 | 0 | 0 | 1 | 4 | 1105 |
| 93 | -0.147978 | 443.777 | 925 | 109 | 34 | 32 | 0 | 0 | 1 | 4 | 1105 |
| 94 | -0.149188 | 446.774 | 923 | 111 | 34 | 32 | 1 | 0 | 1 | 4 | 1105 |
| 95 | -0.150398 | 449.679 | 922 | 112 | 34 | 32 | 1 | 0 | 1 | 4 | 1105 |
| 96 | -0.151449 | 452.173 | 922 | 112 | 33 | 33 | 1 | 0 | 1 | 4 | 1105 |

The maximum displacement of the control node is 0.151 m . Beyond that displacement the analysis cannot run, because of the severe strength loss of the elements of the building. The most extended damages (beyond E) are found in beams in the South-West side of the building at the floor levels $A, B$ and $C .39$ hinges exceed life safety limit state.

The columns C11 and C18 face significant strength degradation
Nonlinear Static Analysis along + Y Axis (Modal Distribution of Lateral Loads)

Figure 6.22 a) Pushover Curve (Modal Distribution of Lateral Loads along + Y Axis) b) ATC-40 Capacity Spectrum-ADRS (Modal Distribution of Lateral Loads along +Y Axis)

Performance Point: $\mathrm{V}=561.429 \mathrm{KN} D=-0.183 \mathrm{~m}, \mathrm{~S}_{\mathrm{a}}=0.076 \mathrm{~g}, \mathrm{~S}_{\mathrm{d}}=0.158 \mathrm{~m}$

Figure 6.23 Deformed Shape of the Structure at Performance Point-Step 66 (Modal Distribution of Lateral Loads along +Y Axis)

Table 6.12 Hinges Limit State Results at Performance Point (Step 66)

| Step | Displacement m | BaseForce KN | AtoB | BtoIO | toL | LStoCP | CPtoC | CtoD | DtoE | BeyondE | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 65 | -0.182084 | 560.028 | 905 | 108 | 60 | 31 | 0 | 0 | 1 | 0 | 1105 |
| 66 | -0.183984 | 562.945 | 905 | 108 | 60 | 31 | 0 | 0 | 1 | 0 | 1105 |
| 67 | -0.185884 | 565.861 | 903 | 107 | 61 | 33 | 0 | 0 | 1 |  | 1105 |
| 68 | -0.187784 | 568.675 | 901 | 109 | 60 | 34 | 0 | 0 | 1 | 0 | 1105 |
| 69 | -0.189684 | 571.472 | 900 | 109 | 61 | 34 | 0 | 0 | 1 | 0 | 1105 |

At the performance point (step 66), there are 32 hinges that exceed life safety limit state. The total of those are found in beams, except one which is found in Column C18 and one in column C11 that faces significant strength degradation ( D to E ).

Nonlinear Static Analysis along -Y Axis (Modal Distribution of Lateral Loads)

| 86 | 0.051681 | 603.424 | 984 | 87 | 25 | 8 | 0 | 1 | 0 | 0 | 1105 |

At the performance point step 84, only 8 hinges exceed life safety limit state. This analysis causes the less damage in comparison to all the other pushover analyses. In addition the lowest base shear force and displacement to the structure is obtained at its performance point.

The results of a hinge are shown in order to indicate the hinge backbone curve. It is taken from beam B30 of floor A ( 9.03 m ) and the pushover analysis with modal lateral load distribution along $-Y$ axis. It is shown that when the performance point is reached (step 84) the hinge status (for the degree of freedom M3 which is crucial for the beams) is between the life safety and collapse prevention limit states.

Figure 6.26 Hinge Results-Backbone Curve

In the figures 6.27 and 6.28, the maximum displacement per floor level and per distribution of the lateral loads, along $X$ and $Y$ axis are shown.

Figure 6.27 Maximum Displacement per Height along X axis for Uniform and Modal Distribution of Lateral Loads

Figure 6.28 Maximum Displacement per Height along $\mathbf{Y}$ axis for Uniform and Modal Distribution of Lateral Loads

In the figures 6.29 and 6.30 , the inter-story drift ratios, which is an important indicator of structural behavior in performance-based seismic analysis, are shown for uniform and modal distribution of lateral loads, along $X$ and $Y$ axis.

Figure 6.29 Inter-story Drift Ratios along X Axis for Uniform and Modal Distribution of Lateral Loads

Figure 6.30 Inter-story Drift Ratios along Y Axis for Uniform and Modal Distribution of Lateral Loads

### 6.6 Discussions on the Pushover Analysis Results

- The maximum displacement of the control node is caused by the pushover analysis with uniform distribution of lateral loads along +Y axis ( $\mathrm{D}=0.24 \mathrm{~m}$ ). The maximum base shear force is caused by the pushover analysis with uniform distribution of lateral loads along the -Y axis (V=1739.577KN).
- Performance point is not obtained for the pushover analyses with modal distribution of loads along -X axis and with uniform distribution of loads along +X axis, showing that the capacity of the structure is inadequate and the structure faces very significant damages and strength degradation when the seismic force is imposed along the X axis.
- The highest number of hinges ( 70 hinges) exceeding the life safety limit state is obtained for the pushover analysis with uniform distribution of lateral loads along +Y axis (which also causes the maximum displacements).
- The highest number of hinges ( 9 hinges) beyond E is obtained for the pushover analysis with modal and uniform distribution of lateral loads along $+X$ axis.
- In general the uniform distribution causes 198 hinges to exceed life safety limit state and 21 to lose their residual strength (beyond E), while the modal distribution causes 134 and 13 hinges, respectively. As a result the uniform distribution of lateral loads causes more damages to the structure than the modal distribution.
- The minimum displacement is caused by the pushover analysis with modal distribution of lateral loads along -Y axis ( 0.049681 m ). In addition it causes the minimum number of hinges (8) that exceed the life safety limit state.
- The most severe damages are obtained in beams in floor levels A ( 9.03 m ) and B ( 12.23 m ). Many hinges in those floor levels lose their residual strength and others face significant strength degradation.
- Columns C11 and C18 face the most significant damages since their hinges range from life safety limit state to D (point on hinge backbone
curve defined by FEMA 356), in floor levels $D$ and $E$, for all the analyses. The hinges of the rest of the columns do not exceed the life safety limit state for none of the pushover analyses performed.
- The maximum absolute displacements increase with floor height for both the lateral load distributions and axes. The maximum displacement is observed in Y axis, as mentioned above.
- The uniform distribution of lateral loads causes higher absolute displacements than the modal distribution, for both the axes $X, Y$. However it is shown that their difference is larger in Y axis than in X axis.
- The maximum displacements caused by the pushover analyses with modal distribution of lateral loads are approximately 0.18 m for both the X and $Y$ axis.
- The inter-story drift ratios are larger for uniform distribution of lateral loads, than they are for modal distribution, for both X and Y axis. However it is shown that their difference is larger in $Y$ axis than in $X$ axis.
- The largest inter-story drift ratio is observed along the Y axis and it is approximately $2 \%$, which is far beyond the acceptable limits.
- The uniform distribution of lateral loads causes higher inter-story drift ratios along axis Y (2\%) than along the X axis (1.7\%). However the modal distribution of lateral loads causes higher inter-story drift ratios along axis $\mathrm{X}(1.65 \%)$ than along the axis $Y(1.35 \%)$.
- It is mentioned that the maximum inter-story drift ratios are observed at medium heights of the building, in the floor levels $A$ (9.03M), B (12.23m) and $C(15.43 m)$.

## Chapter 7

## Nonlinear Time-History Dynamic Analyses of the Existing Structure

Time-history analysis is a step-by-step analysis of the dynamic response of a structure to a specified loading that may vary with time. The nonlinear timehistory analysis is highly dependent on the time history used. Thus many nonlinear analyses, using a variety of accelerograms are required, in order to obtain reliable results. The response of the building is directly calculated in discrete time steps.

The dynamic equilibrium equations to be solved are given by:

$$
\begin{equation*}
K u(t)+C \dot{u}(t)+M \ddot{u}(t)=r(t) \tag{34}
\end{equation*}
$$

(CSi, 1995)
Where $K$ is the stiffness matrix, $C$ is the damping matrix and $M$ is the diagonal mass matrix. $u, \dot{u}, \ddot{u}$ are the displacements, velocities and accelerations of the structure and $r$ is the applied load. Here the applied load refers to the ground motion, so the displacements, velocities and accelerations are relative to this ground motion (CSi, 1995).

### 7.1 Nonlinear Characteristics of the structure elements

The nonlinear characteristics of the structure elements are exactly the same as for the pushover analysis.

### 7.2 Earthquake Ground Motion Time-Histories

Three pairs of acceleration time histories are used. They are obtained by the earthquakes of Corinth (1981, magnitude: 6.6), Kalamata (1986, magnitude 6.2) and L'Aquila-Italy (2009 magnitude: 6.3). The acceleration time histories are obtained by the PEER Ground Motion Data Base-Beta version. It is an interactive web based application that allows the user to select sets of ground motion acceleration time series that are representative of design ground
motions. The user may specify the design ground motions in terms of a target response spectrum and the desired characteristics of the earthquake ground motions in terms of earthquake magnitude, source-to-site distance and other characteristics (Pacific Earthquake Engineering Research Center (PEER), 2010).

Consistent pairs of earthquake ground motion records are simultaneously imposed to the structure, along each of the horizontal axes (longitudinal and transverse).

The values of the acceleration time histories are scaled, to the value of $\mathrm{a}_{\mathrm{g}} . \mathrm{S}$, where for seismic zone II and ground type $B$ is $0.24 g \cdot 1.2=0.288 \mathrm{~g}$. According to EN 1998-1 (2004) the zero period response spectrum acceleration values should not be lower than the value of $\mathrm{a}_{\mathrm{g}} . \mathrm{S}$ for the site in question.

In the figures 7.1 to 7.18 , the scaled and non scaled acceleration time-histories and their corresponding response spectrums are shown.

### 7.3 Time-History Function Definition in SAP 2000

The time series shown above are defined in SAP 2000 by the commands:
Define $\Rightarrow$ Function $\Rightarrow$ Time History $\Rightarrow$ (Choose Function Type to Add) $\Rightarrow$ From File

Figure 7.19 Time History Function Definition
Time-histories are defined for the longitudinal and transverse direction of the 3 earthquake events mentioned above.

The loads are combined according to the combinations:
$G+0.3 Q+E x+0.3 E y, G+0.3 Q+E x-0.3 E y, G+0.3 Q-E x+0.3 E y, G+0.3 Q-E x-0.3 E y$, $\mathrm{G}+0.3 \mathrm{Q}+0.3 \mathrm{Ex}+\mathrm{Ey}, \mathrm{G}+0.3 \mathrm{Q}+0.3 \mathrm{Ex}-\mathrm{Ey}, \mathrm{G}+0.3 \mathrm{Q}-0.3 \mathrm{Ex}+\mathrm{Ey}, \mathrm{G}+0.3 \mathrm{Q}-0.3 \mathrm{Ex}-\mathrm{Ey}$

Where it is assumed that the longitudinal time histories are along the X axis and the transverse time histories are along the $Y$ axis of the structure.

### 7.4 Load Case Definition in SAP 2000

The time-histories are added on the vertical loads, already acting, at the end of the previous case. When performing a nonlinear time-history analysis, such as for earthquake loading, it is necessary to start from a nonlinear static state, such as due to gravity loading ( CSi , 1995). The output time step size and the number of output time steps are set according to the time history time step size
and number of steps. The nonlinear analysis will internally solve the equations of motion at each output time step and at each load function time step. The values of the time-history functions are multiplied by $9.81 \mathrm{~m} / \mathrm{s}^{2}$ since the values imported are in g . The value 2.943 shown in the figure 7.20 is the result of the multiplication $9.81 \cdot 0.3$, where the value 0.3 is due to the load combination.

Figure 7.20 Load Case Definition: L'Aquila. Load Combination: G+0.3Q+0.3Ex+Ey
The time-history motion type is set to transient, indicating that the applied load is considered as a one-time event, with a beginning and end.

The time-history type is set to direct integration. Direct Integration is applied to the equations of motion, without the use of modal superposition. Direct integration results are extremely sensitive to time-step size in a way that is not true for modal superposition (CSi, 1995).

In direct integration time-history analysis, the damping in the structure is modeled using a full damping matrix, which allows coupling between modes to be considered (CSi, 1995).

Mass and Stiffness Proportional Damping

Figure 7.21 Mass and Stiffness Proportional Damping Coefficients
For each direct integration time-history load case, proportional damping coefficients that apply to the structure as a whole may be specified. The damping matrix is calculated as a linear combination of the stiffness matrix, scaled by a coefficient $C_{K}$ and the mass matrix scaled by a coefficient, $C_{M}$.

Here, the coefficients are specified by the two fundamental periods of the structure.

$$
\begin{equation*}
C=C_{M} \cdot M+C_{K} \cdot K \tag{35}
\end{equation*}
$$

(Katsikadelis, 2012)

The nonlinear equations are solved iteratively in each time step, which may require reforming and resolving the stiffness and damping matrices. The iterations are carried out until the solution converges.

The Newmark time integration method is used and the parameters gamma and beta are set to 0.5 and 0.25 , respectively.

### 7.5 Results of Nonlinear Time-History Analyses

The nonlinear time-history analyses cause significant damages to the structure. In the following figures, the deformed shapes of the most unfavorable load combination for each of the three earthquake events are presented.

## L'Aquila Earthquake Event

Figure 7.22 Earthquake Event: L'Aquila. Most Unfavourable Load Combination: G+0.3Q+Ex+0.3Ey

The most unfavorable load combination, that causes the most severe damages to the structure, due to the L'Aquila Earthquake event is the $\mathrm{G}+0.3 \mathrm{Q}+\mathrm{Ex}+0.3 \mathrm{Ey}$. (However all the load combinations of L'Aquila earthquake event cause hinges in columns to exceed limit state E).

In the columns $\mathrm{C} 1, \mathrm{C} 6, \mathrm{C} 11, \mathrm{C} 12, \mathrm{C} 18, \mathrm{C} 19, \mathrm{C} 20$ there are hinges that have no residual strength (beyond E). Two hinges of column C 18 have no residual strength. The hinges of $\mathrm{C} 12, \mathrm{C} 18, \mathrm{C} 19, \mathrm{C} 20$ are formed in the floor levels A and B.

In addition, C2 faces significant strength degradation (one hinge in the limit state: collapse prevention to collapse), and C11 is above life safety limit state.

Summarizing, hinges in 7 columns exceed limit state E and in total (including the 7 above E) 9 columns exceed life safety limit state.

In addition there are 21 hinges beyond E in beams in several floor levels.

As a result of the extended damages, probably the building is collapsed.

Figure 7.23 Displacement Time-History of the Center of Mass (joint 130) of the Approachable Roof due to L'Aquila Earthquake Event

Figure 7.24 Hysteretic Loop of base shear force along X-Displacement along X of joint 130-(center of mass of the approachable roof) - L'Aquila

## Corinth Earthquake Event

Figure 7.25 Earthquake Event: Corinth. Most Unfavourable Load Combination: G+0.3Q-Ex-0.3Ey

The most unfavorable load combination that causes the most severe damages to the structure, due to Corinth Earthquake event is the G+0.3Q-Ex-0.3Ey. (However all the load combinations of Corinth earthquake event cause hinges in columns to exceed life safety limit state. Many load combinations cause hinges in columns to exceed limit state E . There are hinges that exceed limit state E in beams for all the load combinations).

In columns $\mathrm{C} 1, \mathrm{C} 6, \mathrm{C} 10, \mathrm{C} 11, \mathrm{C} 13, \mathrm{C} 14$ there are hinges that have no residual strength (beyond E). The hinges in C10 are formed in floor level D and the hinges in columns C13 and C14 are formed in floor levels A and B. In addition
there are 16 hinges beyond $E$ in beams. Summarizing, hinges in 6 columns exceed limit state E .

Display Plot Function Traces (corinth)

Figure 7.27 Hysteretic Loop of base shear force along X-Displacement along X of joint 130-(center of mass of the approachable roof)- Corinth

## Kalamata Earthquake Event

Figure 7.28 Earthquake Event: Kalamata. Most Unfavourable Load Combination: G+0.3Q-Ex-0.3Ey

The most unfavorable load combination that causes the most severe damages to the structure, due to Kalamata Earthquake event is the G+0.3Q-Ex-0.3Ey. In columns C1 and C18 are formed hinges between life safety and collapse prevention limit states. In column C11 there is hinge between $C$ and $D$ limit states. (However all the load combination of Corinth event cause hinges in columns and beams to exceed life safety limit state).

The building faces the lesser damages due to Kalamata Earthquake in comparison to the Corinth and the L'Aquila earthquake events.

Figure 7.29 Displacement Time-History of the Center of Mass (joint 130) of the Approachable Roof due to Kalamata Earthquake Event

Figure 7.30 Hysteretic Loop of base shear force along $X$ - Displacement along $X$ of joint 130-(center of mass of the approachable roof)- Kalamata

In the figures 7.31 and 7.32 the maximum absolute displacements of each floor level for the three earthquake events are shown for axis X and Y .

Figure 7.31 Maximum Absolute Displacement per Floor Level for Earthquakes imposed along the $X$ axis

Figure 7.32 Maximum Absolute Displacement per Floor Level for Earthquakes imposed along the $Y$ axis

In the figures 7.33 and 7.34 the inter-story drift ratios for the three earthquake events are shown for axes X and Y .

Figure 7.33 Inter-story Drift Ratios along $X$ axis

Figure 7.34 Inter-story Drift Ratios along Y axis

In the following figures the time-histories of the bending moments and shear forces along axis $X(M 3, V 2)$ and along axis $Y(M 2, V 3)$ of the column $C 20$, for each floor level, for the L'Aquila earthquake event are shown.

Figure 7.35 Time-History of Bending Moments of Column C20 along axis X (M3-3)

Figure 7.36 Time-History of Shear Forces of Column C20 along axis X (V2-2)

Figure 7.37 Time-History of Bending Moments of Column C20 along axis Y (M2-2)

Figure 7.38 Time-History of Shear Forces of Column C20 along axis Y (V3-3)

### 7.6 Discussions on Nonlinear Time History Analyses Results

- All the earthquake events, form hinges in columns that exceed life safety limit state.
- The earthquake events of Corinth and L'Aquila for each one of the load combinations, form hinges in 6 and 7 columns respectively, that exceed limit state E . In addition many hinges beyond E are formed in beams. Thus the building is probably collapsed when Corinth or L'Aquila acceleration time-histories are imposed to the structure. The lesser damages are caused by the Kalamata earthquake event.
- The most extended damages, no matter which earthquake event is imposed, are observed when the main axis of the acceleration timehistory is imposed along the X axis of the structure.
- It is shown from the displacement time history of the joint 130 (closer to the center of mass of the roof) that the maximum displacement for the L'Aquila earthquake event is -0.19 m and occurs at 5 sec approximately, the maximum displacement for the Corinth earthquake event is -0.26 m and occurs at 11 sec approximately and the maximum displacement for the Kalamata earthquake event is -0.23 m and occurs at 5 sec approximately.
- From the maximum absolute displacements per floor level and axis of the building, it is shown that the maximum absolute displacements increase with height.
- The maximum absolute displacements on the structure are caused by the Corinth earthquake event for both the axis X and Y , while the L'Aquila earthquake event causes the minimum.
- The highest inter-story drift ratios for Corinth and Kalamata earthquake events are observed in the floor levels A-B for both axes ( $\mathrm{X}, \mathrm{Y}$ ), while for L'Aquila they are observed at floor levels $\mathrm{A}-\mathrm{B}$ and $\mathrm{B}-\mathrm{C}$.
- In general the ratios are higher along the $X$ axis than they are along the $Y$ axis. It does make sense, since the worst load combinations, for which the drift ratios are calculated, are taken along the main axis $X$ (because those combinations caused the most significant damages).
- The inter-story drift ratios are proportional to the maximum displacements caused by the earthquake. The higher the displacements the higher the inter-story drift ratios. Thus the higher inter-story drift ratios in both X and Y axes are caused by the Corinth earthquake event in the most floor levels.
- The maximum inter-story drift ratios are observed for Corinth earthquake event along the X axis in the floor levels $\mathrm{A}-\mathrm{B}(1.7 \%)$.
- It is shown from the time histories of the forces of the column C20 that the highest values for all the magnitudes, are approximately occurring at 18 sec . M3-3=-135KNm, V2-2=350KN, M2-2=-1380KNm, V3-3=-1150KN. The maximum of V3-3 is observed in the mezzanine floor level, while the maximum of the others is observed in the A floor level. It is shown from the hinge's backbone curve that prior the $18^{\text {th }}$ sec the member is highly rotated, thus in the $18^{\text {th }}$ sec the strength of the element is lost. The loss of the strength last from 18.4 to 18.8 sec. The M2-2 (along $Y$ axis) is higher than M3-3 (along $X$ axis), even if the main axis of the imposed seismic accelerogram is the X axis. This is because the C 20 is in the edge of the building and there is no other member beyond (to the West) C20 in the Y axis, that could contribute to resist against the earthquake motion.

Figure 7.39 Deformed shape and hinges results of the Columns C19,C20,C21 due to the L'Aquila earthquake event (Load Combination: G+0.3Q+Ex+0.3Ey)

### 7.7 Conclusions on the Assessment of the Bearing Capacity of the

 StructureFrom the nonlinear static (pushover) and the nonlinear dynamic analyses, it is concluded that the building faces significant and extended damages in many members. The structure cannot satisfy the current codes and the seismic action it is subjected to, thus seismic retrofitting is necessary. The assessment shows that the building is probably collapsed when subjected to the Corinth or the L'Aquila earthquake events.

The building has no lateral force resisting system.
Too many elements-columns and beams, exceed the life safety limit state.

Hinges formed in columns C1, C6, C10, C11, C12, C13, C14, C18, C19, C20 exceed limit state $E$ (beyond $E$ ). In other words, the 10 out 23 columns of the structure have no residual strength.

The most severe damages are observed in floor levels $A$ and $B$ and in the top of the columns, in the West, South-West and South side of the building.

The maximum inter-story drift ratios from all of the analyses are approximately $2 \%$ along the $Y$ axis, due to pushover analysis with uniform distribution of lateral loads. The ratio of $2 \%$ is too high. The inter-story drift ratios are generally higher than permitted.

The Corinth earthquake event causes the highest inter-story drift ratios (1.7\% along the $X$ axis in floor levels $A-B$ ), of the three earthquake events.

The pushover analyses with modal distribution of lateral loads along the $-X$ axis and the uniform distribution along the $+X$ axis do not find a performance point, indicating that the structure capacity is inadequate.

The maximum displacement of the center of mass of the approachable roof is 0.26 m , due to the Corinth earthquake event, which is too high.

## Chapter 8

## Strengthening of the Structure

The target of the retrofitting is the life safety performance level. None of the columns is allowed to exceed life safety limit state.

The structure has no lateral force resisting system, leading to excessive lateral deformations and the elements have inadequate ductility to sustain resulting deformations. In addition the strength and stiffness of the structure is inadequate and the under-strength elements that require modifications are too many.

Thus, the global structural strengthening and stiffening in combination with local modification of inadequate column elements are the chosen strategies. By structural stiffening the deformation demand of the structure is reduced, and by local modification the ductility and strength of the members are increased.

The retrofitting systems that are used to satisfy the above strategies are the addition of shear walls within the existing frames and the local modification of the inadequate columns by concrete jacketing.

To that purpose 7 shear walls and jackets to 17 out of 23 columns are added.
The shear walls are added within the existing frames:

Shear wall 1: between the columns C16 and C17

Shear wall 2: between the columns C4 and C9

Shear wall 3: between the columns C1 and C6
Shear wall 4: between the columns C18 and C19

Shear wall 5: between the columns C20 and C15

Shear wall 6: between the columns C2 and C3

Shear wall 7: between the columns C13 and C14

The jackets are applied to the columns: C1, C2, C3, C4, C5, C6, C9, C11, C13, C14, C15, C16, C17, C18, C19, C20, C23.

In other words the jackets are applied to the columns at the sides of the added shear walls, to the columns at the corners of the building and to the column C11.

All the interventions take into account the architectural plan drawings, so the functionality of the hotel is not influenced. All the rooms existing before the intervention will be fully functional after the construction of the shear walls and column jackets at the positions shown in the figure 8.1.

Figure 8.1 Structural Interventions- Addition of Shear walls and jackets

The dimensions of the shear walls are:

Shear wall 1: $2.65 \mathrm{~m} \times 0.30 \mathrm{~m}$

Shear wall 2: $3.20 \mathrm{~m} \times 0.30 \mathrm{~m}$

Shear wall 3: $2.60 \mathrm{~m} \times 0.40 \mathrm{~m}$
Shear wall 4: $3.20 \mathrm{~m} \times 0.40 \mathrm{~m}$

Shear wall $5: 2.00 \mathrm{~m} \times 0.30 \mathrm{~m}$

Shear wall 6: $2.30 \mathrm{~m} \times 0.30 \mathrm{~m}$

Shear wall 7: $3.60 \mathrm{~m} \times 0.30 \mathrm{~m}$

Figure 8.2 Section of Shear Wall 5 (section designer)

The reinforcing steel of the shear walls is $\Phi 16 / 0.125 \mathrm{~m}$ and in the corners $\Phi 20$.

The shear walls are considered to be monolithically connected to the frames they are added in, and their joints are included to the diaphragmatic behaviour of each floor level.

The width of the jacket is 10 cm and the reinforcing steel is $16 \Phi 16+4 \Phi 20$. Confining reinforcement is also added $\Phi 10 / 10$ (2 ties in height and width).

The bar cover is 4 cm .

Figure 8.3 Jacket of Column C5 at the floor level E. Jacket Width:10cm, Reinforcing Steel: 16Ф16+ 4Ф20 Bar Cover: 4cm

The jackets may be modelled using section designer of SAP2000. The existing section is added on the new section (which parameters are the new-concretereinforcing steel etc.).

The concrete of the new members is C20/25 and the reinforcing steel is S500. Their parameters are given below:

## Concrete:

Characteristic compressive cylinder strength of concrete at 28 days: $f_{c k}=20 \mathrm{MPa}$ Characteristic compressive cube strength of concrete at 28 days: $\mathrm{f}_{\mathrm{ck}, \text { cube }}=25 \mathrm{MPa}$ Mean value of concrete cylinder compressive strength: $\mathrm{f}_{\mathrm{cm}}=28 \mathrm{MPa}\left(\mathrm{f}_{\mathrm{cm}}=\mathrm{f}_{\mathrm{ck}}+8\right)$

Mean value of axial tensile strength of concrete: $\mathrm{f}_{\mathrm{ctm}}=2.2 \mathrm{MPa}$

Young's modulus: $\mathrm{E}_{\mathrm{cm}}=30 \mathrm{GPa}$

Stain at maximum unconfined compressive strength, $\mathrm{f}^{\prime}$ : $\varepsilon_{\mathrm{c} 1}=2$ \%o

Ultimate unconfined stain capacity: $\varepsilon_{\mathrm{cu} 1}=3,5$ \%o

Reinforcing Steel:

The S500 reinforcing steel minimum yield point (fy) is 500 MPa and the minimum tensile stress (fu) 550 MPa .
$\mathrm{E}=200 \mathrm{GPa}$, Strain at onset of strain hardening: 0.02, ultimate strain capacity: 0.12 , weight per unit volume: $78.5 \mathrm{KN} / \mathrm{m}^{3}$

### 8.1 Modal Analysis Results

A modal analysis of the retrofitted structure is performed. The secant stiffness of the elements is used.

Table 8.1 Modal Participating mass ratios of the retrofitted structure using the secant stiffness

| )utputCas | StepTyp | StepNur | Period | UX | UY | UZ | RX | RY | RZ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Text | Text | Unitless | Sec | Unitless | Unitless | Unitless | Unitless | Unitless | Unitless |
| MODAL | Mode | 1 | 1.265863 | 0.13965 | 0.39769 | 9.2E-07 | 0.26175 | 0.07473 | 0.00013 |
| MODAL | Mode | 2 | 1.117586 | 0.33231 | 0.11996 | 2.1E-06 | 0.07892 | 0.18677 | 0.06803 |
| MODAL | Mode | 3 | 0.936403 | 0.05646 | 0.01853 | $1.6 \mathrm{E}-06$ | 0.01362 | 0.03049 | 0.45089 |
| MODAL | Mode | 4 | 0.34637 | 0.0187 | 0.0905 | 5.5E-06 | 0.05201 | 0.00765 | 0.00152 |

In addition a modal analysis of the retrofitted structure when the stiffness proposed by the table 4.1 of KANEPE is performed. It would be interesting to compare the periods and the participating mass ratios when the stiffness proposed by the table 4.1 and the secant stiffness are used.

Table 8.2 Modal Participating mass ratios of the retrofitted structure using the stiffness proposed by the table 4.1 of KANEPE

| TA BLE: | Modal Participating Mass Ratios |  |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :---: | :---: | :---: | :---: | :---: |
| utputCasStepTypeStepNum | Period | UX | UY | UZ | RX | RY | RZ |  |  |
| Text | Text | Unitless | Sec | Unitless | Unitless | Unitless | Unitless | Unitless | Unitless |
| MODAL | Mode | 1 | 0.78999 | 0.07806 | 0.4583 | $1.4 \mathrm{E}-06$ | 0.30989 | 0.04359 | 0.00086 |
| MODAL | Mode | 2 | 0.69811 | 0.33722 | 0.05088 | $3.2 \mathrm{E}-06$ | 0.03324 | 0.20011 | 0.12206 |
| MODAL | Mode | 3 | 0.55175 | 0.11497 | 0.02705 | $7.2 \mathrm{E}-06$ | 0.02199 | 0.06177 | 0.38467 |
| MODAL | Mode | 4 | 0.20998 | 0.00771 | 0.10858 | $1.5 \mathrm{E}-07$ | 0.06414 | 0.00406 | 0.00214 |

It can be seen that the periods do have significant differences.
For the nonlinear analyses presented in the following, the secant stiffness is used.

### 8.2 Wall System Check

The structural system of the retrofitted building is a wall system, since lateral loads are mainly resisted by vertical shear walls, whose shear resistance at the building base exceeds $65 \%$ of the total shear resistance of the whole structural system (in this definition, the fraction of shear resistance may be submitted by the fraction of shear forces in the seismic design situation).

Modal Response Spectrum analyses are performed. The seismic action is imposed on the X and on the Y axis separately.

Table 8.3 Wall System Check

|  | Seismic Action <br> Along X axis | Seismic Action <br> Along Y axis |
| :---: | :---: | :---: |
| Percentage of <br> shear force <br> taken by shear <br> walls | 0.702 (V2-2) | 0.654 (V3-3) |

## Chapter 9

## Nonlinear Static (Pushover) Analysis Results of the Retrofitted Structure

The significance of the effect of higher modes should be examined as described in chapter 5.

Table 9.1 Higher Mode Participation Check for Earthquake Imposed along the X Axis

| Earthquake imposed along $X$ axis |  |  |  |
| :---: | :---: | :---: | :---: |
| Floor Level | Shear Force <br> (KN) Capturing the $\mathbf{9 0 \%}$ of mass participation | Shear Force <br> (KN) <br> Fundamental <br> mode ( X axis) | Variation (\%) |
| Ground Floor | 2386.32 | 1944.68 | 1.22 |
| A | 1449.09 | 1263.19 | 1.14 |
| B | 1213.12 | 1111.23 | 1.09 |
| C | 1033.83 | 825.89 | 1.25 |
| D | 843.92 | 658.43 | 1.28 |
| E | 700.14 | 536.08 | 1.30 |

Table 9.2 Higher Mode Participation Check for Earthquake Imposed along the y Axis

| Earthquake imposed along Y axis |  |  |  |
| :---: | ---: | :--- | ---: |
|  | Shear Force <br> (KN) Capturing <br> the 90\% of <br> mass <br> participation | Shear Force <br> (KN) <br> Fundamental <br> mode <br> (Y axis) | Variation <br> (\%) |
| Ground <br> Floor | 2478.70 |  | 2348.52 |

It is concluded that the higher mode effects are not significant; since the shear in any story resulting from the modal response spectrum analysis, considering modes required to obtain $90 \%$ mass participation, does not exceed $130 \%$ of the corresponding story shear, considering only the fundamental mode response in either direction.

A Pushover analysis is performed exactly as described in the chapter 6.

Nonlinear Static Analysis along + Y Axis (Modal Distribution of Lateral Loads)

Figure 9.13 a) Pushover Curve (Modal Distribution of Lateral Loads along +Y Axis) b) ATC-40 Capacity Spectrum-ADRS (Modal Distribution of Lateral Loads along +Y Axis)

Performance Point: $\mathrm{V}=6895.38 \mathrm{KN} D=0.205 \mathrm{~m}, \mathrm{~S}_{\mathrm{a}}=0.200 \mathrm{~g}, \mathrm{~S}_{\mathrm{d}}=0.125 \mathrm{~m}$

Figure 9.14 Deformed Shape of the Structure at Performance Point-Step 79 (Modal Distribution of Lateral Loads along +Y Axis)

Table 9.9 Hinges Limit State Results at Performance Point (Step 79)

| Step | Displacemen m | aseForce <br> KN | AtoB | BtoIO IOtoLSLStoCPCPtoC CtoD |  |  |  |  | DtoE | BeyondE | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 77 | 0.201696 | 6840.175 | 774 | 161 | 97 | 24 | 0 | 0 | 0 | 0 | 1056 |
| 78 | 0.203896 | 6872.531 | 773 | 161 | 97 | 25 | 0 | 0 | 0 | 0 | 1056 |
| 79 | 0.206096 | 6904.41 | 771 | 161 | 98 | 26 | 0 | 0 | 0 | 0 | 1056 |
| 80 | 0.208296 | 6935.646 | 771 | 158 | 100 | 27 | 0 | 0 | 0 | 0 | 1056 |
| 81 | 0.210496 | 6966.5 | 769 | 158 | 101 | 28 | 0 | 0 | 0 | 0 | 1056 |

There are 26 hinges that exceed the life safety limit state. However no hinge exceeds life safety limit state in columns. Hinges between the limit states immediate occupancy and life safety are formed in two columns (JC2, JC4).

## Nonlinear Static Analysis along -Y Axis (Modal Distribution of Lateral Loads)

Figure 9.15 a) Pushover Curve (Modal Distribution of Lateral Loads along -Y Axis) b) ATC-40 Capacity Spectrum-ADRS (Modal Distribution of Lateral Loads along -Y Axis)

Performance Point: $\mathrm{V}=6381.76 \mathrm{D}=-0.220 \mathrm{~m}, \mathrm{~S}_{\mathrm{a}}=0.191 \mathrm{~g}, \mathrm{~S}_{\mathrm{d}}=0.126 \mathrm{~m}$

Figure 9.16 Deformed Shape of the Structure at Performance Point-Step 84 (Modal Distribution of Lateral Loads along -Y Axis)

Table 9.10 Hinges Limit State Results at Performance Point (Step 84)

| S | Displacemen <br> m | BaseForce <br> KN | AtoB | BtoI | OtoLS | to |  | CtoD | DtoE | BeyondE | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 82 | -0.217619 | 6346.62 | 773 | 142 | 103 | 38 | 0 | 0 | 0 | 0 | 1056 |
| 83 | -0.219819 | 6374.353 | 771 | 140 | 104 | 41 | 0 | 0 | 0 | 0 | 1056 |
| 84 | -0.222019 | 6401.453 | 769 | 137 | 107 | 43 | 0 | 0 | 0 | 0 | 1056 |
| 85 | -0.224219 | 6427.897 | 769 | 136 | 108 | 43 | 0 | 0 | 0 | 0 | 1056 |
| 86 | -0.225354 | 6441.526 | 767 | 138 | 105 | 46 | 0 | 0 | 0 | 0 | 1056 |

At the performance point (step 84), 43 hinges exceed limit safety limit state. However all of them are in beams and there is no hinge exceeding life safety limit state in column or shear wall. There are hinges between the limit states immediate occupancy and life safety in three columns (JC6, C10, C12).

Figure 9.9 a) Pushover Curve (Modal Distribution of Lateral Loads along +X Axis) b) ATC-40 Capacity Spectrum-ADRS (Modal Distribution of Lateral Loads along +X Axis)

Performance Point: $\mathrm{V}=1081.86 \mathrm{KN}, \mathrm{D}=0.019 \mathrm{~m}, \mathrm{~S}_{\mathrm{a}}=0.587 \mathrm{~g}, \mathrm{~S}_{\mathrm{d}}=0.062 \mathrm{~m}$

Figure 9.18 Maximum Displacement per Height along Y axis for Uniform and Modal Distribution of Lateral Loads

Figure 9.19 Inter-story Drift Ratios along X Axis for Uniform and Modal Distribution of Lateral Loads

Figure 9.20 Inter-story Drift Ratios along Y Axis for Uniform and Modal Distribution of Lateral Loads

### 9.1 Discussions on Pushover Analyses Results

Only beam-hinges exceed the life safety limit state, for the analyses of modal distribution of lateral loads along the $-Y$ and $+Y$ axes. Nearly no hinge exceeds life safety limit state by other analyses.

The maximum displacement of the control node of the building is caused for modal distribution of lateral loads along the -Y axis ( -0.22 m ). In addition, the maximum number of hinges exceeding life safety limit state is observed by this analysis (however as mentioned earlier no hinge exceeds life safety limit state in column or shear wall).

The maximum absolute displacements of the building per height due to the uniform distribution of lateral loads are higher than due to the modal distribution of lateral loads, along the $X$ axis.

The maximum absolute displacements of the building per height due to the modal distribution of lateral loads are higher than due to the uniform distribution of lateral loads, along the Y axis.

The inter-story drift ratios due to the uniform distribution of lateral loads are higher than due to the modal distribution of lateral loads, along the $X$ axis.

The inter-story drift ratios due to the modal distribution of lateral loads are higher than due to the uniform distribution of lateral loads, along the Y axis.

## Chapter 10

## Nonlinear Time-History Dynamic Analyses Results of the Retrofitted Structure

Nonlinear time-history analyses performed as described in chapter 7. There is no hinge in columns, shear wall or beam that exceeds life safety limit state. The results of load combinations that are presented in chapter 7, are also presented in this chapter, in order to be comparable.

## L'Aquila Earthquake Event

Figure 10.1 Earthquake Event: L'Aquila, Load Combination: G+0.3Q+Ex+0.3Ey No column-hinge is exceeding immediate occupancy limit state.

Figure 10.16 Time-History of Bending Moments of Column C20 along axis Y (M2-2)

Figure 10.17 Time-History of Shear Forces of Column C20 along axis Y (V3-3)

### 10.1 Discussions on Nonlinear Time-History Analyses Results of the Retrofitted Structure

- No hinge in column or shear wall exceeds life safety limit sate for none of the earthquake events the structure is subjected to.
- It is shown by the time-histories of the displacement of the center of mass of the approachable roof (joint 130) that the maximum displacement $(-0.14 \mathrm{~m})$ is caused by the L'Aquila earthquake event at approximately 5 seconds, while for both Corinth and Kalamata the maximum displacement ( -0.12 m ) is caused at approximately 4 seconds.
- The charts of the maximum absolute displacements show that the maximum absolute displacements increase with the building's height.
- The maximum absolute displacement is caused by the L'Aquila earthquake event ( 0.14 m ) along the $X$ axis.
- Along the X axis, the maximum absolute displacements observed are caused by the L'Aquila earthquake event, while the displacements caused by Corinth and Kalamata are lower and approximately equal.
- Along the Y axis, the maximum absolute displacements of the structure are caused by the earthquake events of Kalamata and L'Aquila, while those caused by Corinth are significantly lower.
- The inter-story drift ratios are generally higher along the X axis than they are along the Y axis.
- The maximum inter-story drift ratio is caused by the L'Aquila earthquake event ( $0.8 \%$ approximately) at the floor levels B-C, along the X axis.
- The inter-story drift ratios are proportional to the maximum absolute displacements. Thus the higher drift ratios are caused by the L'Aquila earthquake event in X and Y (Kalamata is close enough along Y ) axes, and the lower by Corinth earthquake event.
- The time-histories of the forces of C20 per height due to the L'aquila earthquake event show that the maximum V2 (along X ), M3 (along Y ), V3 (along Y) occur at the ground level, while the peak of the M2 (along $X$ ) occurs at the floor level $B$. In addition it is observed that the time the peaks occur is approximately 5 seconds, when the maximum
displacement due to the L'aquila earthquake event is caused to the structure.

### 10.2 Conclusions on the Assessment of the Bearing Capacity of the Retrofitted Structure

- From the nonlinear static (pushover) and the nonlinear dynamic analyses, it is concluded that the building is satisfactory retrofitted to the performance level of life safety, since there is no hinge in columns or shear walls exceeding life safety limit state.
- The maximum displacement of the building is caused for the pushover analysis with modal distribution of lateral loads along the $-Y$ axis ( 0.22 m ). In addition, the maximum number of hinges exceeding life safety limit state (43) is observed by this analysis. However as mentioned earlier there is no hinge exceeding life safety limit state in column or shear wall.
- The maximum inter-story drift ratio (1.3\%) is caused by the pushover analyses along the Y axis with a modal distribution of lateral loads at floor levels B-C and C-D.

## Chapter 11

## Shear Resistance Checks

### 11.1 Check of Shear Resistance of Shear Walls

According to EN 1992-1 (2004), in regions of the member that $\mathrm{V}_{\mathrm{Ed}} \leq \mathrm{V}_{\mathrm{Rd}, \mathrm{c}}$ no calculated shear reinforcement is necessary. $\mathrm{V}_{\mathrm{Ed}}$ is the design shear force in the section considered resulting from external loading. In regions where $\mathrm{V}_{\mathrm{Ed}}>\mathrm{V}_{\mathrm{Rd}, \mathrm{c}}$ sufficient shear reinforcement should be provided in order that $\mathrm{V}_{\mathrm{Ed}} \leq \mathrm{V}_{\mathrm{Rd}, \mathrm{c}}$.

The design value for the shear resistance $\mathrm{V}_{\mathrm{Rd}, \mathrm{c}}$ is given by:
$V_{R d, c}=\left[C_{R d, c} k\left(100 \rho_{1} f_{c k}\right)^{1 / 3}+k_{1} \sigma_{c p}\right] b_{w} d$
With a minimum of
$V_{R d, c}=\left(v_{\text {min }}+k_{1} \sigma_{c p}\right) b_{w} d$

Where:
$\mathrm{f}_{\mathrm{ck}}$ is in MPa
$k=1+\sqrt{\frac{200}{d}} \leq 2,0$ with d in mm
(38) (EN 1992-1 ,2004)
$\rho_{1}=\frac{A_{s l}}{b_{w} d} \leq 0.02$
$A_{s l}$ is the area of the tensile reinforcement, which extends $\geq\left(l_{b d}+d\right)$ beyond the section considered
$b_{w}$ is the smallest width of the cross-section in the tensile area (mm)
$\sigma_{\mathrm{cp}}=\mathrm{N}_{\mathrm{Ed}} / \mathrm{A}_{\mathrm{C}}<0.2 \mathrm{f}_{\mathrm{cd}}[\mathrm{MPa}]$
$N_{E d}$ is the axial force in the cross-section due to loading ( $N_{E d}>0$ for compression)
$\mathrm{A}_{\mathrm{c}}$ is the area of concrete cross section ( $\mathrm{mm}^{2}$ )
$\mathrm{V}_{\mathrm{Rd}, \mathrm{c}}$ is [ N ]

The values of $\mathrm{C}_{\mathrm{Rd}, \mathrm{c}}, \mathrm{v}_{\text {min }}$ and $\mathrm{K}_{1}$ according to the Greek National Annex of EN 1992-1 are $0.18 / \mathrm{Y}_{\mathrm{c}}$, given from $\mathrm{v}_{\text {min }}=0.035 \mathrm{k}^{3 / 2} \mathrm{fck}^{1 / 2}, 0.15$ respectively.

And $\gamma_{c}$ is 1.5 for concrete, for persistent and transient design situations according to table 2.1N of EN 1992-1.

In the following table the check of shear resistance of the shear wall 7 is shown.

The maximum values of $\mathrm{V}_{\mathrm{Ed}}$ obtained by the analyses are used.
Table 11.1 Check of Shear Resistance of Sheart Wall 7

| $\mathrm{C}_{\mathrm{Rd}, \mathrm{c}}$ | 0.12 |
| :--- | :--- |
| $\mathrm{f}_{\mathrm{ck}}(\mathrm{MPa})$ | 20 |
| $\mathrm{~d}(\mathrm{~mm})$ | 3570 |
| k | 1.23 |
| $\mathrm{~b}_{\mathrm{w}}(\mathrm{mm})$ | 300 |
| $\mathrm{~A}_{\mathrm{sl}}\left(\mathrm{mm}^{2}\right)$ | 2814.86 |
| $\rho_{1}$ | 0.0026 |
| $\mathrm{~N}_{\mathrm{Ed}}(\mathrm{N})$ | 1661331 |
| $\left.\mathrm{Ac}(\mathrm{mm})^{2}\right)$ | 1080000 |
| $\sigma_{\mathrm{cp}}(\mathrm{MPa})$ | 1.538 |
| K 1 | 0.15 |
| $\mathrm{~V}_{\min }$ | 0.215 |
| $\mathrm{~V}_{\mathrm{Rd}, \mathrm{c}}(\mathrm{KN})$ | 521.952 |
| $\mathrm{~V}_{\mathrm{Ed}}(\mathrm{KN})$ | 302.615 |

It is shown that $\mathrm{V}_{\mathrm{Ed}} \leq \mathrm{V}_{\mathrm{Rd}, \mathrm{c}}$ for shear wall 7 , so the shear wall resistance to shear forces is adequate and shear reinforcement is not required. According to the
same procedures the checks are performed for all the shear walls and the results are shown in table 9.2.

Table 11.2 Results of Checks of Shear Resistance of Shear Walls

| Shear Walls | $\mathrm{V}_{\mathrm{Ed}}(\mathrm{KN})$ | $\mathrm{V}_{\text {Rd, }}(\mathrm{KN})$ | $\mathrm{V}_{\mathrm{Rd}} \quad(\mathrm{KN})$ <br> (When Shear Reinforcement is Required) |
| :---: | :---: | :---: | :---: |
| Shear Wall 1 | 668.05 | 508.73 | 842.65 |
| Shear Wall 2 | 1001.40 | 558.17 | 1019.54 |
| Shear Wall 3 | 514.44 | 582.74 |  |
| Shear Wall 4 | 817.13 | 689.99 | 1019.54 |
| Shear Wall 5 | 163.27 | 304.80 |  |
| Shear Wall 6 | 225.18 | 391.92 |  |
| Shear Wall 7 | 302.62 | 521.95 |  |

### 11.2 Check of Shear Resistance of Existing Members

According to EN 1998-3 (2005), the cyclic shear resistance, $\mathrm{V}_{\mathrm{R}}$, decreases with the plastic part of ductility demand, expressed in terms of ductility factor of the transverse deflection of the shear span of the chord rotation at member end: $\mu_{\Delta}{ }^{\mathrm{pl}}=\mu_{\Delta}-1$. For this purpose $\mu_{\Delta}{ }^{\mathrm{pl}}$ may be calculated as the ratio the plastic part of the chord rotation, $\theta$, normalized to the chord rotation at yielding, $\theta_{y}$, calculated as described in section 6.2

The following expression may be used for the shear strength, as controlled by the stirrups, accounting for the above reduction (units: MN and meters):
$V_{R}=\frac{1}{\gamma_{e l}}\left[\frac{h-x}{2 L_{v}} \min \left(N ; 0.55 A_{c} f_{c}\right)+\left(1-0.05 \min \left(5 ; \mu_{\Delta}^{p l}\right)\right)\left[0.16 \max \left(0.5 ; 100 \rho_{\text {tot }}\right)\left(1-0.16 \min \left(5 ; \frac{L_{v}}{h}\right)\right) \sqrt{f_{c}} A_{c}+V_{W}\right]\right]$
(39) (EN 1998-3, 2005)
where:
$Y_{\mathrm{el}}=1.15$ for primary seismic elements and 1 for secondary,
$h$ is the depth of the cross-section,
x is the compression zone depth,
N is the compressive axial force (positive, taken being zero for tension)
$L_{V}=M / V$ is the ratio moment/shear at the end section
$A_{c}$ is the cross-section area, taken as being equal to $b_{w} d$ for a cross-section with a rectangular web of width (thickness) $b_{w}$ and structural depth $d$,
$\mathrm{f}_{\mathrm{c}}$ is the concrete compressive strength (should further be divided by the partial factor for concrete in accordance with EN1998-1:2004, 5.2.4,

Ptot is the total longitudinal reinforcement ratio,
$\mathrm{V}_{\mathrm{w}}$ is the contribution of transverse reinforcement to shear resistance, taken as being equal to: (for cross-sections with rectangular web of width (thickness) $b_{w}$ )

$$
\begin{equation*}
V_{W}=\rho_{W} b_{W} z f_{y W} \tag{40}
\end{equation*}
$$

Where:
$\rho_{\mathrm{w}}$ is the transverse reinforcement ratio,
$z$ is the length of the internal level arm
$f_{y w}$ is the yield stress of the transverse reinforcement (for primary seismic elements should further be divided by the partial factor for steel in accordance with EN 1998-1:2004, 5.2.4.

The shear resistance of the column C 10 is checked according to the procedure described above. The column C 10 is chosen because it is one of the columns that concrete jacket is not applied. The shear resistance is checked in two parts of the column, in the ground floor level, where the maximum shear forces are
observed-but no plastic deformation occurs, and in the floor level C-where plastic hinge in the life safety limit state is formed.

C 10 at the ground floor: $0.45 \times 0.454 \Phi 20+4 \Phi 16$
C10 at floor level C: 0.3X0.34Ф16

Table 11.3 Shear check of the column C10 (no jacket is applied)

|  | Column C10 at the <br> Ground Floor Level | Column C10 at the Floor <br> C Level |
| :--- | :--- | :--- |
| $\mathrm{Yel}_{\mathrm{el}}$ | 1.15 | 1.15 |
| $\mathrm{~h}(\mathrm{~m})$ | 0.45 | 0.3 |
| $\mathrm{~N}(\mathrm{MN})$ | 0.71445 | 0.33096 |
| $\mathrm{~L}_{\mathrm{v}}(\mathrm{M} / \mathrm{V})$ | 1.708 | 1.6 |
| $\mathrm{~A}_{\mathrm{c}}\left(\mathrm{m}^{2}\right)$ | 0.1935 | 0.084 |
| $\mathrm{f}_{\mathrm{c}}(\mathrm{MPa})$ | 16.667 | 16.667 |
| Ptot | 0.0106506 | 0.0095744 |
| $\mathrm{r}_{\mathrm{w}}$ | 0.0005195 | 0.0011968 |
| $\mathrm{~b}_{\mathrm{w}}(\mathrm{m})$ | 0.45 | 0.3 |
| $\mathrm{z}(\mathrm{m})$ | 0.41 | 0.28 |
| $\mathrm{f}_{y \mathrm{w}}(\mathrm{MPa})$ | 220 | 220 |
| $\mathrm{~V}_{\mathrm{w}}(\mathrm{MN})$ | 0.02108 | 0.00221 |
| $\mathrm{~V}_{\mathrm{w}}(\mathrm{KN})$ | 21.088 | 22.117 |
| $\mathrm{~V}_{\mathrm{R}}(\mathrm{MN})$ | 0.1052161 | 0.034765 |
| $\mathrm{~V}_{\mathrm{R}}(\mathrm{KN})$ | 105.216 | 34.764 |
| $\mathrm{~V}_{\text {Ed }}(\mathrm{KN})$ | 87.93 | 31.24 |

The shear resistance is adequate in both cases, since $\mathrm{V}_{\mathrm{Ed}}<\mathrm{V}_{\mathrm{R}}$

## Chapter 12

## Retrofitted and Non-retrofitted Building Comparison

The results of the modal analyses of the retrofitted and the non-retrofitted building are compared, when both the secant stiffness and the values of stiffness of the table 4.1 are used.

The results of the nonlinear static analyses, including the pushover curves, the hinges' limit state results, the maximum absolute displacements and the interstorey drift ratios, between the retrofitted building and the non retrofitted building are compared.

In addition, the corresponding results of the nonlinear dynamic analyses and the forces on the column C20 between the retrofitted and the non-retrofitted building are compared.

### 12.1 Modal Analyses Comparison

## Stiffness proposed in table 4.1:

## Non-Retrofitted:

Table 12.1 Modal Participating Mass Ratios of the Non-Retrofitted Structure using the Stiffness proposed in Table 4.1 of KANEPE

| StepType | StepNum | Period | UX | UY | $\mathbf{C Z}$ | RX | RY | RZ |

## Secant Stiffness:

## Non-Retrofitted:

Table 12.3 Modal Participating Mass Ratios of the Non-Retrofitted Structure using the Secant Stiffness

| StepType StepNum |  | Period | UX | UY | UZ | RX | RY | RZ |
| :--- | ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Text | Unitless | Sec | Unitless | Unitless | Unitless | Unitless | Unitless | Unitless |
| Mode | 1 | 2.639646 | 0.32636 | 0.08261 | $4.702 \mathrm{E}-08$ | 0.06237 | 0.19121 | 0.09604 |
| Mode | 2 | 2.368858 | 0.05254 | 0.42026 | 0.000006131 | 0.31761 | 0.03047 | 0.03167 |
| Mode | 3 | 1.942065 | 0.13775 | 0.0017 | 0.000001648 | 0.00139 | 0.0805 | 0.35319 |

## Retrofitted:

Table 12.4 Modal Participating Mass Ratios of the Retrofitted Structure using the Secant Stiffness

| StepTypeitepNur | Period | UX | UY | UZ | RX | RY | RZ |  |
| :--- | ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Text | Unitless | Sec | Unitless | Unitless | Unitless | Unitless | Unitless | Unitless |
| Mode | 1 | 1.265863 | 0.13965 | 0.39769 | $9.152 \mathrm{E}-07$ | 0.26175 | 0.07473 | 0.00013 |
| Mode | 2 | 1.117586 | 0.33231 | 0.11996 | $2.116 \mathrm{E}-06$ | 0.07892 | 0.18677 | 0.06803 |
| Mode | 3 | 0.936403 | 0.05646 | 0.01853 | $1.595 \mathrm{E}-06$ | 0.01362 | 0.03049 | 0.45089 |

- It is observed that either the secant stiffness is used, or the stiffness proposed by the table 4.1, the periods are significantly reduced when the building is retrofitted.
- The fundamental periods of the structure when secant stiffness is used, are much higher (approximately 1 sec for the non-retrofitted and 0.5 sec for the retrofitted) than when the stiffness proposed by the table 4.1 of KANEPE is used, for both the retrofitted and the non-retrofitted building, indicating that the secant stiffness, leads to much more flexible structures.
- The highest mass participating ratio of the fundamental period $T_{1}$, of the non-retrofitted building, when both secant and the stiffness of the table 4.1 are used, is along axis X . The corresponding mass participating ratio of the retrofitted building is along axis Y .

### 12.2 Pushover Analyses

### 12.2.1 Comparison of the Capacity Curves of the Non-Retrofitted and

 the Retrofitted Building

Figure 12.1 Pushover Analysis-Uniform Distribution of Lateral Loads along +X Axis

Figure 12.2 Pushover Analysis-Uniform Distribution of Lateral Loads along -X Axis

Figure 12.3 Pushover Analysis-Uniform Distribution of Lateral Loads along +Y Axis

Figure 12.4 Pushover Analysis-Uniform Distribution of Lateral Loads along -Y Axis

Figure 12.5 Pushover Analysis-Modal Distribution of Lateral Loads along +X Axis

Figure 12.6 Pushover Analysis-Modal Distribution of Lateral Loads along -X Axis

Figure 12.7 Pushover Analysis-Modal Distribution of Lateral Loads along +Y Axis

Figure 12.8 Pushover Analysis-Modal Distribution of Lateral Loads along -Y Axis
From the comparison of the pushover curves of the non-retrofitted and the retrofitted building, it is obvious that the capacity and the ductility of the retrofitted building are much higher.
12.2.2 Hinges Limit States Results

| Hinges Results |  |
| :---: | :---: |
| Retrofitted Building | Non Retrofitted Building |
| - None of the hinges that exceed the limit state of life safety is formed in column or shear wall. <br> - Hinges that exceed life safety limit state do not exceed collapse prevention limit state. None of the hinges exceeds collapse prevention limit state. <br> - The pushover analysis with a modal distribution of lateral loads along -Y formed 43 hinges between the limit states life safety and collapse prevention (all beam-hinges). | - According to every one of the pushover analyses results, hinges that exceed life safety limit state are formed in columns. <br> - The columns C11 and C18 face significant strength degradation. <br> - Many hinges that exceed limit state E are formed in beams. <br> - The most severe damages are concentrated in the West, South-West and South side of the building, in floor levels $A$ and $B$. <br> - The pushover analyses with a modal distribution of lateral loads along $-X$ and a uniform distribution along $+X$ cannot reach a performance point, due to significant strength loss and damage. <br> - The pushover analyses with a modal distribution of lateral loads along $+X$ and a uniform distribution along $+X$ form 9 hinges beyond E . |

### 12.2.3 Maximum Absolute Displacements Comparison

- The higher the floor level under consideration, the higher the maximum absolute displacements.
- It is observed that the maximum absolute displacements of the retrofitted building are always lower than of the non-retrofitted (except in the case of modal distribution of lateral loads along U2(Y axis)).
- The maximum absolute displacements of the top, both for the retrofitted and the non retrofitted building are observed along U2. For the retrofitted building it is caused by a modal lateral load distribution, while for the non-retrofitted it is caused by a uniform lateral load distribution.
- Along the $\mathrm{U} 1(\mathrm{X}$ axis), the maximum absolute displacements of the retrofitted building are much lower than the non-retrofitted for both the uniform and modal lateral loads distribution, for all the floor levels.

Figure 12.9 Maximum Absolute Displacements along X axis for Uniform and Modal Distribution of Lateral Loads for the Non-Retrofitted and the Retrofitted Building

Figure 12.10 Maximum Absolute Displacements along Y axis for Uniform and Modal Distribution of Lateral Loads for the Non-Retrofitted and the Retrofitted Building

### 12.2.4 Inter-Storey Drift Ratios Comparison

- The maximum inter-storey drift ratios of the non retrofitted building are too high, much higher than the permitted values.
- The inter-storey drift ratios of the retrofitted building are significant lower (except for the pushover analysis with a modal distribution of lateral loads along U2), than those of the non-retrofitted.
- The maximum inter-story drift ratios are observed at the floor levels A-B$C$ of the non-retrofitted building and at the floor levels B-C-D of the retrofitted. In general the ratios are higher around at mid heights of the building, than they are at the top and at the bottom.
- The highest ratios are observed along the $Y$ axis for both the nonretrofitted and the retrofitted building.

Figure 12.11 Inter-Storey Drift Ratios along $X$ axis for Uniform and Modal Distribution of Lateral Loads for the Non-Retrofitted and the Retrofitted Building

Figure 12.12 Inter-Storey Drift Ratios along $Y$ axis for Uniform and Modal Distribution of Lateral Loads for the Non-Retrofitted and the Retrofitted Building

### 12.3 Nonlinear Time-History Dynamic Analyses

### 12.3.1 Hinges Limit States

| Hinges Results |  |
| :--- | :--- |
| Retrofitted Building | Non Retrofitted Building |
| $\begin{array}{l}\text { • No hinge in column or shear } \\ \text { wall exceeds life safety limit } \\ \text { state. }\end{array}$ | $\begin{array}{l}\text { - Hinges exceeding life safety } \\ \text { limit state are caused by all the } \\ \text { earthquake events imposed to } \\ \text { the structure and for each one } \\ \text { of the combinations of the }\end{array}$ |
|  | $\begin{array}{l}\text { seismic forces. }\end{array}$ |
|  | $\begin{array}{l}\text { There are 6 columns whose } \\ \text { hinges exceed limit state E due } \\ \text { to Corinth earthquake event }\end{array}$ |
| and 7 columns due to L'Aquila. |  |$\}$| In addition many beam-hinges |
| :--- |
| beyond E are caused by both |
| earthquakes. Probably the |
| building is collapsed. |

### 12.3.2 Comparison of the Maximum Absolute Displacements of the

 Non-Retrofitted and the Retrofitted Building due to the Earthquake events: L'Aquila, Corinth, Kalamata- The displacements of the retrofitted building are significantly lower than those of the non-retrofitted (especially along the X axis).
- Both the retrofitted and the non-retrofitted face larger displacements along the X axis than along the Y axis.
- The maximum absolute displacements of the retrofitted building are caused by the L'Aquila earthquake event and those of the non-retrofitted by the Corinth earthquake event.
- The lower maximum absolute displacements of the non-retrofitted are caused by the L'aquila earthquake event for both the X and Y axis. The lower maximum absolute displacements of the retrofitted are caused by the Kalamata and Corinth along the X axis, and by Corinth along the Y axis.

Figure 12.13 Maximum Absolute Displacements along $X$ axis of the Non-Retrofitted and the Retrofitted Building due to the Earthquake events: L'Aquila, Corinth, Kalamata

Figure 12.14 Maximum Absolute Displacements along $\mathbf{Y}$ axis of the Non-Retrofitted and the Retrofitted Building due to the Earthquake events: L'Aquila, Corinth, Kalamata

### 12.3.3 Comparison of the Inter-storey Drift Ratios of the of the NonRetrofitted and the Retrofitted Building due to the Earthquake events:

## L'Aquila, Corinth, Kalamata

- The inter-story drift ratios of the retrofitted building are lower than those of the non-retrofitted, for both X and Y axes. The ratios are corresponding to the maximum displacements.
- The maximum inter-story drift ratios of the non-retrofitted are observed at the floor levels A-B-C-D, while those of the retrofitted are observed at the floor levels B-C-D.
- Both the retrofitted and the non-retrofitted face higher inter-story drift ratios at the mid heights of the building than at the top and bottom.
- The highest inter-storey drift ratio of the non-retrofitted building is given by the Corinth earthquake event, while the highest of the retrofitted is given by L'Aquila earthquake events for both X and Y axes.

Figure 12.15 Inter-Storey Drift Ratios along X axis for the Non-Retrofitted and the Retrofitted Building due to the Earthquake events: L'Aquila, Corinth, Kalamata

Figure 12.16 Inter-Storey Drift Ratios along Y axis for the Non-Retrofitted and the Retrofitted Building due to the Earthquake events: L'Aquila, Corinth, Kalamata

### 12.3.4 Comparison of the Maximum Forces along the Column C20 of the Retrofitted and the Non-Retrofitted Building (L'Aquila Earthquake Event)

It can be seen from the following figures that in some cases (excepting the extremely high values observed) the envelope of the forces of the retrofitted column is higher than the corresponding forces of the non-retrofitted (especially along $X$ axis above mezzanine floor level).

On the one hand the seismic action imposed in the building remains the same, on the other hand the stiffness of the retrofitted element is increased, thus it takes higher forces. However, not only the stiffness, but also the strength of the element is increased, thus it is able to sustain the higher forces.

The extremely high values of the forces of the non-retrofitted element are obtained when a plastic hinge is being formed. Probably the hinges of neighboring elements are unloading, so the redistribution of forces inside the structure cause extremely high values of bending moments and shear forces within column C20.

The higher strength and ductility of the retrofitted structure ensures that hinges remain in the elastic area or they get into plastic in lower-acceptable levels. As a result the extremely high values of the non-retrofitted building are not observed for the retrofitted.

Figure 12.17 Envelope of the Bending Moments of Column C20 along Axis X (M3-3) per Floor Level of the Non-Retrofitted (blue) and the Retrofitted (red) Building

Figure 12.18 Envelope of the Shear Forces of Column C20 along Axis X (V2-2) per Floor Level of the Non-Retrofitted (blue) and the Retrofitted (red) Building

Figure 12.19 Envelope of the Bending Moments of Column C20 along Axis Y (M2-2) per Floor Level of the Non-Retrofitted (blue) and the Retrofitted (red) Building

Figure 12.20 Envelope of the Shear Forces of Column C20 along Axis Y (V3-3) per Floor Level of the Non-Retrofitted (blue) and the Retrofitted (red) Building

## Chapter 13

## Summary and Conclusions

### 13.1 Summary

The aim of this project is to assess the bearing capacity of the reinforced concrete hotel and to strengthen it. The hotel was constructed in 1967 in Greece. The building was designed and constructed under the provision of the national codes of Members of Reinforced Concrete (1954) and the Design Code for Earthquake Resistant structures (1959). The code of 1959 did not provide safety against earthquakes in comparison with the modern codes. The hotel is in seismic zone $2\left(Z 2, a_{G R} / g=0.24\right)$. It is a 5 -storey reinforced concrete building with underground floor, ground floor (two levels), mezzanine floor, approachable and non approachable roof. The total number of levels is 11 . Its overall high is 27.53 m , including the non approachable roof, while the typical high of floors is $3.2 m$ (except the underground, ground and mezzanine floor).

The building is modelled using the SAP2000 software. It is general purpose civil engineering software. It is ideal for the analysis and design of any type of structural system.

Firstly, modal response spectrum analysis is performed. The purpose of this type of analysis is to detect possible deficiencies the building would have if it was designed according to the modern codes, and not to assess its bearing capacity. The bearing capacity is assessed by performing nonlinear static and dynamic analyses.

Nonlinear static analyses are performed. The target displacement is calculated according to the ATC-40 method, which is applied automatically by SAP 2000. In addition nonlinear dynamic time-history analyses are performed. Three pairs of acceleration time histories are used. They are the obtained by the earthquakes of Corinth (1981, magnitude: 6.6), Kalamata (1986, magnitude 6.2) and

L'Aquila-Italy (2009 magnitude: 6.3). The acceleration time histories are obtained by the PEER Ground Motion Data Base-Beta version. The acceleration time-histories are scaled.

The assessment of the bearing capacity shows that the structure requires rehabilitation, since the building faces significant damages due to its inadequate bearing capacity. Thus 7 shear walls and concrete jackets to 17 out of 23 columns are added to the structure.

The analyses described above are repeated. The retrofitted structure satisfies the target performance level-life safety, when seismic action corresponding to seismic return period of 475 years, or the scaled L'Aquila, Corinth, Kalamata acceleration time-histories are imposed.

### 13.2 Conclusions

- It is a very flexible structure. The fundamental period of the nonretrofitted structure is $1.63 \mathrm{sec}(30 \%$ along X$)$ when the stiffness of the elements according to the table 4.1 is used, while it is $2.64 \mathrm{sec}(33 \%$ along $X$ ) when the secant stiffness is used. The stiffness of the retrofitted structure is higher, thus the fundamental period is lower, $0.79 \mathrm{sec}(46 \%$ along Y ) when the stiffness of the elements according to the table 4.1 is used, while it is $1.27 \mathrm{sec}(40 \%$ along $Y$ ) when the secant stiffness is used, indicating that the structure remains flexible although the rehabilitation.
- The use of the secant stiffness leads to higher flexibility and periods because the part of the sections that is considered effective is lower than when the values of the table 4.1 are used. When the values of the table 4.1 are used, the modification factor of SAP 2000 is set to 0.8 or 0.6 for columns (internal and outer respectively), 0.5 for cracked shear walls and 0.4 for beams. When the secant stiffness is used, the average values of the modification factor Keff/Kel is 0.23 for columns and 0.13 for beams. As a result, it is indicated that only a small part of the section is considered effective, uncracked and contributes to earthquake
resistance. The effective section of the beams is considered even smaller than the effective section of the columns.

## Non-Retrofitted Structure:

- The geometric dimensions of the sections of the elements of the nonretrofitted building (both columns and beams) are not adequate in comparison with the modern codes and there is no lateral force resisting system.
- The building exceeds the life safety performance level, since the hinges of its columns exceed it. More plastic hinges are formed in beams than in columns.
- The most severe damages are observed in the West, South-West and South side of the building at the floor levels A and B.
- The low stiffness of the building leads to high maximum absolute displacements per height and high inter-storey drifts along both $X$ and $Y$ axis.
- The earthquake events of L'Aquila and Corinth probably cause the collapse of the building, since hinges in 7 and 6 columns, respectively, exceed limit state E-they have no residual strength and cannot sustain loads.
- The non-retrofitted building has inadequate strength, low stiffness and ductility.
- Global and local retrofitting is required. The elements' strength and ductility should be increased. The stiffness should be increased to reduce the lateral displacements and the inter-storey drift ratios. The ductility of the elements should be increased, so they will be able to absorb the seismic energy more effectively.

## Retrofitted Structure:

- The rehabilitation of the building is global, since the acceleration timehistories imposed are from very intense and catastrophic earthquakes. In
addition the time histories are scaled and the L'Aquila earthquake influences especially the flexible buildings.
- The 7 shear walls add strength and stiffness to the structure. The concrete jackets increase the bearing capacity, the flexural/shear strength and the deformation capacity of the elements.
- The higher modes are insignificant, thus the pushover analysis is permitted.
- The retrofitted building is a wall system building, since more than $65 \%$ of the shear force is taken by the shear walls.
- The retrofitted building satisfies the design criteria of the life safety performance level, since no hinge in columns exceeds the life safety limit state.
- The bearing capacity of the retrofitted building is much higher than the bearing capacity of the non-retrofitted.
- The maximum absolute displacements and the inter-story drift ratios per floor level of the retrofitted structure are lower than those of the nonretrofitted, since the shear walls increase the stiffness of the structure.
- The shear walls are able to sustain the shear forces as shown by the shear check.
